1 - To be OR - key Danish contributors to the history of OR, IFORS and EURO

Graham Rand

The surprising fact that EURO24, the 33rd EURO conference, is the first hosted by Denmark, provides the opportunity to give a personal reflection on the Danish contribution to OR history. There will be an emphasis on four individuals who have played a significant role in the development of OR theory and professional infrastructure. Three of these individuals will be revealed at the lecture. For now, it is sufficient to say that the lecture is in honour of my dear friend Jakob Krarup, who passed away last year. He was greatly looking forward to the conference being held in his own city.

From this description it will be obvious that this will not be a standard keynote address. However, there may be one, or three, equations included. That is a clue to one of the other three individuals whose contribution will be noted.

1 - Regularized Interior Point Methods for Convex Programming

Spyridon Pougkakiotis

Large-scale convex optimization is integral to several application domains, given its amenability to efficient solution methods and its versatile modeling capabilities. Interior Point Methods (IPMs) represent a widely adopted class of optimization techniques for solving convex problems due to their ability to yield accurate solutions with a polynomial complexity guarantee. However, challenges such as numerical inaccuracy and ill-posedness of the underlying optimization problem can impede their performance.

To address these challenges, researchers have explored regularized versions of IPMs, which exhibit improved robustness in practical scenarios. Despite the practical success of regularized IPMs, a comprehensive theoretical understanding has been lacking until recently.

In this talk, we present an infeasible IPM combined with the Proximal Method of Multipliers (PMM). The resulting algorithm (IP-PMM) is interpreted as a primal-dual regularized IPM, suitable for solving convex programming problems. We apply few iterations of the interior point method to each sub-problem of the proximal method of multipliers. Once a satisfactory solution of the PMM sub-problem is found, we update the PMM parameters, form a new IPM neighbourhood, and repeat this process.

Crucially, we demonstrate the polynomial complexity of the algorithm for a broad class of convex problems under standard assumptions, marking a significant advancement as the first polynomial complexity

result for a primal-dual regularized IPM. By inheriting the polynomial complexity of IPMs and the numerical stability of PMMs, IP-PMM offers a promising solution.

To enhance the applicability of our approach, we discuss general-purpose preconditioning strategies for efficiently solving the associated linear systems within IP-PMM. Subsequently, we present numerical results spanning a diverse range of convex programming problems, showcasing the benefits of regularization in IPMs and affirming the reliability and efficiency of the proposed IP-PMM algorithm.

2 - Demand Management in Shared Mobility Systems

Matthias Soppert

Shared mobility systems like car sharing and bike sharing have become an attractive and wide-spread type of urban mobility over the past decades. The biggest challenge regarding the profitable operation of such systems is the occurring dynamic imbalance between supply and demand, which stems from fluctuating demand patterns and spatially unbalanced vehicle movements. To counter these imbalances, the scientific literature so far has focused on the supply-sided control approach by means of active vehicle relocation. In this dissertation, demand management is proposed as a cost-efficient alternative, in which the system's demand side is influenced through pricing and availability control. On the one hand, specific practice-relevant problems are addressed and solved. On the other hand, general modeling and solution approaches are developed, which can be transferred to related optimization problems for tactical and operational control of shared mobility systems. Extensive numerical studies, including case studies of Europe's largest car sharing company Share Now, demonstrate that demand management can be implemented successfully in shared mobility systems.

3 - Enhancing classification and regression trees. A mathematical optimization approach

Cristina Molero-Río

Contrary to classic classification and regression trees, built in a greedy heuristic manner, designing the tree model through an optimization problem allows us to easily include desirable properties in Machine Learning in addition to prediction accuracy. We present a Non-Linear Optimization approach that is scalable with respect to the size of the training sample, and illustrate this flexibility to model several important issues in Explainable and Fair Machine Learning. These include sparsity, as a proxy for interpretability, by reducing the amount of information necessary to predict well; fairness, by aiming to avoid predictions that discriminate against sensitive features such as gender or race; the cost-sensitivity for groups of individuals in which prediction errors are more critical, such as patients of a disease, by ensuring an acceptable accuracy performance for them; local explainability, where the goal is to identify the predictor variables that have the largest impact on the individual predictions; as well as data complexity in the form of observations of functional nature. The performance of our approach is illustrated on real and synthetic data sets.

1 - Research on Optimization of Air Material Joint Allocation under Multi-level Inventory Model

Chenyang Wang, Jianwu Xue, Jiawei Tuo

With the rapid development of the aviation industry, airlines of various countries have to store a large amount of aviation materials at airports and maintenance bases in order to ensure the normal operation of flights. However, this has resulted in a backlog of aircraft inventory, which undoubtedly imposes significant depreciation and administrative costs on airlines. In this paper, we address the aircraft material

allocation problem faced by airlines under the multi-base and multi-tier aircraft material inventory distribution model, and mathematically abstract the factors affecting the allocation of aircraft material. By constructing a mathematical optimization model with the lowest total avionics management cost of the whole inventory system as the objective function, and the avionics guarantee rate and downtime as the constraints, we aim to optimize the number of avionics allocation of the avionics base as a whole, in order to reduce the amount of avionics inventory, so as to achieve the purpose of reducing the inventory cost. Taking China Eastern Airlines, one of the three major airlines in China, the high-priced turnover parts of aviation materials as the research object, the mathematical simulation model is prepared using Matlab software. It confirms that the two-level inventory avionics management model proposed in this paper has certain advantages and provides a new solution for airlines in finding the balance between avionics protection and avionics management cost.

2 - Classifying import containers based on cargo contents: an unsupervised text classification

Ying Xie, Dongping Song

Post unloading from vessels, import containers are temporarily stacked at seaport yards before being transported to inland customers. A significant challenge faced at container ports is the optimal storage of import containers, including proximity to out-terminals and minimizing reshuffling needs. However, uncertainties surrounding collection times and transportation mode pose challenges for port operators. Nevertheless, port operators possess knowledge of each import container's contents upon unloading from vessels. An interesting research question arises: can cargo content information be leveraged to enhance container storage management? Addressing this question entails categorising import containers into manageable classes based on cargo contents. This study tackles the challenge of categorising a high variety of cargo contents, often exceeding 100K unique items, using the Standard International Trade Classification as labels. Our novel unsupervised text classification approach employs pretrained GloVe Word Embeddings and Cosine Similarity for label assignment. This integration offers an efficient approach to generate training datasets in data-scarce scenarios. Additionally, we address data imbalance through three strategies: upsampling/downsampling, class weights, and weighted loss function. Leveraging the Transformers based neural-network models on enriched and balanced datasets, we achieve promising results in accurately classifying container content.

3 - Long-term maintenance optimization for integrated mining operations

Yingying Yang

Maintenance activities are inevitable and costly in integrated mining operations. Conducting maintenance may require the whole system, or sub-units of the system, to be shut down temporarily. These maintenance activities not only disrupt the unit being shut down, but they also have consequences for inventory levels and product flow downstream. In this paper, we consider an interconnected mining system in which there are complicated maintenance relationships and stock accumulation at intermediate nodes. We propose a time-indexed mixed-integer linear programming formulation to optimize the long-term integrated maintenance plan and maximize the total throughput. We also devise an algorithm, which combines Benders decomposition and Lagrangian relaxation, to accelerate the computational speed. To validate our mathematical model, we perform simulations for a real-world case study in the iron ore industry. The results show that our method can yield better solutions than CPLEX optimization solver alone in faster time.

4 - Approximate dynamic programming for inland empty container inventory management

Sangmin Lee, Trine Krogh Boomsma

Empty container repositioning (ECR) is crucial in handling global trade imbalances by managing the flow and storage of empty containers to effectively accommodate customer demands and returns. We formulate a Markov decision process that accounts for practical characteristics of ECR, including multiple transportation modes and lead times,

and uncertainty and serial correlation in net container inflows. To determine a cost-minimising repositioning policy for real-life scenarios, we employ a stochastic approximate dynamic programming approach, integrated with statistical techniques, such as convex regression and Latin hyper cube sampling. We highlight the advantages of incorporating exogenous variables into the approximation model. A case study with historical daily data on empty container in- and out-flows demonstrates the effective control of on-hand inventory levels while optimising holding and leasing costs. Moreover, we quantify the benefits of leveraging all transportation modes, with cost reduction potentials of up to 26.05%. Finally, we evaluate the robustness of our algorithm under variations in key parameters.

Invited session

Chair: *Erkut Arican*

1 - Mixture of Experts-based Coherent Probabilistic Forecasts for Hierarchically related Time Series

Junyong Lee, Jun-Geol Baek

Coherent probabilistic forecasting, where the goal is to forecast multivariate time series that have hierarchical aggregation is important for accurate decision making in real world application. Recent work has focused on end-to-end fashion that simultaneously learns from all time series in the hierarchy and comprise the reconciliation step in single trainable model. However, this approach often neglects that distinct advantages of several reconciliation methods, where is adept to identifying temporal characteristics. To address this gap, our study proposes a novel coherent probabilistic forecasting framework with mixture-of-experts (MoE). Employing the MoE framework, our approach effectively captures both regular and irregular temporal dependencies to integrate three diverse strategies: top-down, bottom-up and fully coherent. By introducing different experts, this model can generate forecasts that are probabilistically coherent as well as produce sophisticated forecasts that encompass diverse temporal dynamics. An empirical evaluation on real world hierarchical time series datasets demonstrates comparable advantages of the proposed approach.

2 - Using long short-term memory network for human body depth image motion recognition and abnormal behavior analysis in long-term care environment

JongChen Chen

Long-term care has become one of the problems that must be addressed in today's society, and falls are one of the problems often encountered in long-term care. However, most previous studies have used accelerometers to detect falls in older adults. Since this sensor must be placed on the body of the elderly, its effect is quite limited in situations where the willingness to wear it is extremely low. This study uses deep image recognition technology to conveniently track the real-time behavior of the elderly and reduce the problems caused by accidents under the appropriate protection of the subjects' privacy. This research uses a Long Short-Term Memory Network (LSTM) to identify daily human movements and detect abnormal behaviors (such as falls). In this study, two scenarios were tested. The first is to invite ten healthy people to perform in a laboratory that simulates long-term exposure. Each subject performed nine actions that might occur in the long-term care environment. The second scenario is to apply the database established in the first scenario to an actual long-term photo field. The experimental results show that under the simulated laboratory, the overall performance is quite good. In contrast, in the actual long-term photo field, the performance of motion recognition will be reduced due to the influence of occlusions

3 - Contrastive Transfer Learning Based on Damage Propagation for Remaining Useful Life Prediction

Seunghwan Song, Jeena Son, Junyong Lee, Jun-Geol Baek

Remaining useful life (RUL) prediction is a crucial task in prognostics and health management (PHM), gaining increasing importance in industrial applications. However, the accuracy of RUL predictions in real-world industrial can be compromised due to data imbalance and discrepancies in data characteristics caused by varying operational conditions. Inspired by the idea of transfer learning, this study proposes a novel RUL prediction framework that utilizes damage propagation and contrastive transfer learning. At first, the proposed method differentiates between health and degradation states within source domain data on a window basis, employing the augmented Dickey-Fuller (ADF) test and acceleration graphs. Then, it predicts the RUL by training on the history subset of degradation state data to maximize the similarity with the multi-scale feature representation of future subset. In the target domain, a comparable strategy is employed but with adjusted sensitivity towards the acceleration graph for more precise state differentiation, enabling the application of the model learned in the source domain to predict the RUL in the target domain. Finally, the proposed method is proved to be effective through two public run-to-failure datasets and one real-world dataset. Demonstrated through experimental results, the proposed method shows superior predictive performance and high transferability, indicating its potential to address the challenges in industrial environments.

Cutting and Packing 1 - 2D rectangular

Stream: Cutting and Packing (ESICUP)

Invited session

Chair: *Sergey Polyakovskiy*

1 - A Constraint Programming Solution to the Guillotine Rectangular Cutting Problem

Sergey Polyakovskiy, Peter Stuckey

The guillotine rectangular cutting problem deals with a single rectangular plate of raw material and a collection of rectangular items to be cut from the plate. Each item is associated with a profit and a demand. The problem searches for a feasible layout of a subset of items on the plate so as to maximize the total profit of the selected items. The guillotine constraint restricts feasible layouts to those that can be obtained via guillotine edge-to-edge cuts that run parallel to an edge of the plate. We propose a novel constraint programming model that is suitable for guillotine cutting with an arbitrary number of stages of alternating horizontal and vertical guillotine cuts. This is an assignment-based model that models guillotine cuts using a constant number of rectangular regions, with some regions allocated to items. It treats the entire plate as a primary region and decides on the guillotine cuts required to split the regions recursively till they produce space for the items. To speed the search, the model explores the strength of cumulative scheduling relaxations of the cutting problem. Our model is a successful alternative to more traditional mixed-integer linear programming (MIP) models. It outperforms a number of state-of-the-art MIPs on a set of small- and moderate-sized benchmark instances and proves optimality for several instances that remain challenging for these MIPs.

2 - Exact Mixed-Integer and Constraint Programming solutions to the two-dimensional bin packing problem with due dates

Milad Dehghan, Sergey Polyakovskiy

The two-dimensional non-oriented bin packing problem with due dates consists in packing a set of rectangular items, which may be rotated by 90 degrees, into identical rectangular bins. The bins have equal processing times. The problem searches for a feasible layout of items so

as to minimize the maximum lateness, with the lateness of each item being the difference between its due date and the completion time of its assigned bin. This minimax problem is computationally challenging: It has a huge solution space with many alternative solutions whose packing configurations are either symmetric or lead to the same solution cost.

We propose two exact approaches. First, we solve the problem as a mixed-integer program (MIP), which we strengthen with a set of feasibility and symmetry-breaking constraints. Our second solution employs constraint programming (CP), and thus benefits from the strength of cumulative scheduling relaxations of the packing problem. Our extensive computational experiments show that MIP, which stands as a more traditional modelling technique within the cutting and packing community, is only successful on small-sized benchmark instances with as few as 60 items. It is outperformed by CP that can solve medium and large instances with up to 100 items in a reasonable time.

3 - Primal and Dual Bounds to the Variable-Sized Two-Dimensional Guillotine Bin Packing Problem

Adam McGregor, Sergey Polyakovskiy

Given a set of small rectangular items and large non-identical rectangular bins, the variable-sized two-dimensional guillotine bin packing problem searches for a feasible packing of the items into the bins, with the items obtained via guillotine cuts. It minimises the total cost of the used bins. We propose a hybrid column generation based matheuristic that solves the problem approximately. Its reduced master problem, which is solved as an integer program, is the classical Dantzig-Wolfe formulation of the VS2BP. The master problem uses a collection of feasible packings that are constructed heuristically during the search process. The initial set of packings is obtained via a heuristic, which selects and packs bins sequentially. This warm-start heuristic employs a look-ahead mechanism that prohibits the search of infeasible directions and enforces directions of likely advance, halting only after the allocated time expires. After this, the incumbent is enhanced by solving a series of pricing problems for each bin type by finding a feasible packing with the largest reduced cost, providing extra columns for the master problem. The search ends either when no solution to the pricing problem is found or when time expires. The packing process is done approximately via an algorithm that hybridizes constraint programming with a heuristic search. Extensive computational experiments provide evidence of good performance of the proposed approach, when compared to the state of the art.

4 - Two-Phase Matheuristic for Assignment and Packing

Jakob Schulte, Daniel Wetzell

We introduce a novel two-phase matheuristic for assignment and packing (2P-MAP) designed to address large-scale assignment and truck loading problems. The scope of our approach involves scenarios with an extensive amount of items requiring assignment to a heterogeneous fleet of trucks and subsequent transportation. The proposed matheuristic strategically tackles the assignment problem in its first phase, followed by a complex truck loading algorithm to validate the assignment solution in the second phase. A distinguishing feature of our heuristic lies in its comprehensive exploration of the solution space, enabling the identification of optimal solutions. Moreover, our approach exhibits seamless adaptability to diverse use cases, given that subproblems are optimized in isolation before being integrated. This approach is motivated by the ROADEF/EURO challenge 2022, where we demonstrate superior performance on select instances, showcasing the potential for significant cost reduction in Renault's Supply Chains.

Portfolio optimization and sustainability

Stream: AI & Innovation in Sustainable Finance

Invited session

Chair: *Filippo Piccotto*

1 - Assessing the impact of Sustainability disclosure in crowdfunding: a Natural Language Processing analysis.

Simona Barone

This paper aims to initiate a dialogue between fintech and sustainability by evaluating the impact of sustainability disclosure on the outcomes of 370 Italian crowdfunding campaigns, collected from the Kickstarter platform between 2015 and 2024. Utilizing an NLP technique called zero-shot classification, we analyzed and classified the blurbs of the campaigns as sustainable, employing a rigorous decision framework. The model utilized was the BART-large model, trained with the MultiNLI dataset. The blurbs classified as sustainable by the model were further validated through human supervision to ensure accuracy. Furthermore, leveraging this classification, we constructed a measure of sustainability, and with a probit regression model, we assessed the impact of sustainability on the success of crowdfunding rounds. Several control variables were included such as the funding goal, campaign duration, blurb length, and the number of investors. The findings indicate that sustainability has a positive and significant impact. Disclosing sustainability information increases the probability of success by 7.73%. Additionally, the number of investors also has a positive and significant effect, while the funding goal has a negative effect. This paper contributes to the literature by providing evidence that sustainability acts as a signal of quality for investors, who are more inclined to invest in sustainable projects, resulting in a higher probability of success.

2 - Enhancing portfolio optimization: an ADMM approach with embedded splitting for scenario-based model predictive control

Marc Weibel

This paper contributes towards developing an efficient algorithm, relying on the Alternating-Direction of Multipliers (ADMM), for solving scenario-based Model Predictive Control arising in multi-period portfolio optimization problems.

We enhance the standard two-set splitting algorithm of the ADMM method by including inequality constraints through a so-called embedded splitting without recourse to an additional splitting set.

We derive an alteration of the termination criterion using the probabilities assigned to the scenarios and provide a convergence analysis.

3 - Behavioural portfolio optimization with sustainable attitudes: an application to the STOXX Europe 600

Filippo Piccotto, Massimiliano Kaucic

Since its introduction, cumulative prospect theory (CPT) has emerged as a significant approach for modeling the irrationality of the decision makers' behavior in complex real situations. Moreover, the interplay between rational finance theories and behavioral finance framework is becoming an intriguing stream of research. To harmonize these two paradigms, a recent contribution in the literature proposed a modification of the PT value function and several alternative probability weighting functions to extend the classical CPT model. The contribution of this paper is twofold. On the one hand, our study delves into these alternative value functions and proposes a CPT-based portfolio optimization model that aligns with rational dynamic asset pricing models while ensuring Environmental, Social, and Governance (ESG) compliance in the investment process. Furthermore, our portfolio design integrates cardinality, box, and budget constraints, while an upper bound for the portfolio turnover maintains control of the transaction costs during the rebalancing phases. On the other hand, to tackle the ensuing optimization problem, we propose a novel hybrid constraint-handling technique embedded into a level-based learning swarm optimizer. Finally, using data from the STOXX Europe 600 Index, we test the profitability of the proposed portfolio optimization strategy. This is a joint work with Professor Massimiliano Kaucic, who will be co-presenter of the paper at the Conference.

Monday, 8:30-10:00 - Room: 10 (building: 116)

Modelling and Economics of Storage Technologies in Energy Markets

Stream: Energy Markets

Invited session

Chair: Valentin Bertsch

1 - On the potential of arbitrage trading on the German intraday power market

Neele Leithäuser, Till Heller, Elisabeth Finhold

Our study focused on the potential of a simple and common risk-averse strategy called greedy pair trading on the German intraday power market. This strategy aims to monetize the flexibility potential of a battery or similar assets. We analyzed real-world order book data from 15 selected days between 2020 and 2022 to estimate the theoretical potential of this strategy when optimal pairs are selected. We also investigated the impact of unbalanced auction wins, which can be a challenge for practical implementation. In our analysis, we compared the greedy approach to the ex post optimal strategy and examined the effect of different frequencies of order book accesses. We found that increasing the frequency of optimization points in the greedy approach did not significantly improve the profit. However, in the ex post optimal strategy, halving the time between trading points resulted in an average profit increase of 30%. Additionally, we observed that a loss of up to 10% of the bids had a negligible impact on the overall profit. Our findings contribute to a better understanding of arbitrage trading on the German intraday market and highlight the advantages of incorporating predictive information and frequent optimization updates.

2 - Extending Least-Squares Monte Carlo to a System-Oriented Study on Storage Operation

Benjamin Böcker, Maike Spilger, Christoph Weber

In energy systems dominated by renewables, the high share of volatile and uncertain electricity generation raises the need for flexibility for balancing supply and demand. Operating a substantial share of energy storage capacities increases the smoothing impacts on electricity prices. Therefore, a system-oriented approach considering uncertainties as well as endogenous price effects is crucial to optimize the operation of energy storage systems in renewable-dominated energy systems. The valuation of energy storage systems under consideration of uncertainties is usually solved by determining optimal operating decisions for given price realizations. Current state-of-the-art approaches, such as least squares Monte Carlo, approximate value functions to recursively determine a dynamic decisions considering the uncertainty of exogenous electricity prices. Our work introduces a hybrid model that combines a least squares Monte Carlo approach with a fundamental model for determining endogenous electricity prices based on a piecewise linear merit order. Here, interactions between storage operations on price determination are explicitly depicted. The developed model thus enables the stochastic valuation of storage operation in the system context and considers the uncertainties of renewable energies, electricity demand, and the technical availability of generation capacities.

3 - Electrical energy storage investment requirements and operating characteristics in a gradually defossilised European power system

Valentin Bertsch, Leonie Sara Plaga, Jonas Finke, Katharina Esser

With the ongoing energy transition in Europe, the share of variable renewable energies (vRE) in the power system increases steadily and different flexibility options gain importance. This work investigates the deployment of supply side flexibility options in the future European power system. We use a cost-minimising energy system model that endogenously optimises the energy-to-power (E2P) ratio and particularly focus on lithium-ion batteries, vanadium redox flow batteries, adiabatic compressed air energy storage and hydrogen storage. We explore the competition of these flexibility options across a broad defossilisation spectrum. Starting at vRE shares of around 50%, we find

non-linearly increasing storage requirements and observe a leap when approaching a zero-emission system, which is mainly driven by hydrogen storage investments. We also find that lithium-ion batteries with E2P ratios between 2 and 6 hours are particularly deployed in countries with high levels of solar power, whereas hydrogen storage with E2P ratios between 300 and 1000 hours is mainly deployed in countries with high levels of wind power. Adiabatic compressed air energy storage with E2P ratios between 15 and 20 hours are only deployed in a completely defossilised system. In addition, we analyse storage operating requirements including operating hours and ramp rates for different defossilisation levels.

4 - Multi-Objective Optimisation for the Inverse Analysis of Design Requirements for Low Technology Readiness Level technologies from an Energy System Perspective *Katharina Esser, Jonas Finke, Valentin Bertsch*

The energy sector is transitioning towards a climate-neutral future based on renewable energy sources. Besides increasing demands for decentralised, flexible, and environmentally friendly technologies, technology innovation will be imperative for this transition, offering unknown potentials. Energy system models are an important tool to address these challenges, using various input parameters for all technologies considered. However, low technology readiness level (TRL) technologies require estimates for those parameters which are usually not possible or poorly verified at an early stage of development. Thus, including low TRL technologies in energy models is associated with high uncertainty and lacking in current research. We develop a new, inverted approach for energy system modelling that considers both the common central-planning perspective of optimal system design and the technical design perspective of technology development. By turning model input parameters such as technology cost or efficiencies into decision variables, these can be used as additional optimisation objectives. A multi-objective optimisation then enables trade-off analyses between overall system cost and requirements for technology development, e.g. the least requirements that would still lead to the use of a technology in a cost-efficient system. We demonstrate the inverted method using the modelling framework Backbone and Carnot Batteries as location-independent energy storage with low TRL.

■ MA-10

Monday, 8:30-10:00 - Room: 11 (building: 116)

EMS logistics

Stream: OR in Health Services (ORAHS)
Invited session

Chair: Melanie Reuter-Oppermann

1 - Operational planning of medical vehicle routes *Nicolas Blandamour*

Medical transport is increasingly important in ensuring access to care for patients unable to travel independently. The patient transport business comprises many aspects in which optimization needs can arise. For example, it could benefit from optimized vehicle routes, improved and more reliable access to patient care, and improved working conditions for ambulance drivers thanks to more predictable schedules.

This presentation will detail an industrial application developed by Hexaly for a French leading healthcare company. This tool optimizes the operational planning of non-emergency patient transport carried out the following day.

The problem consists in assigning vehicles to employees and creating mission rounds for each employee. The underlying optimization problem is related to the Dial-A-Ride Problem. Indeed, one of the key features of non-emergency patient transport is the possibility of transporting several people in the same vehicle at the same time. Employees' schedules are also subject to numerous contractual and regulatory constraints such as breaks.

A typical dataset of the problem corresponds to a daily volume of 500 missions to be planned, with around 50 employees and vehicles available.

The optimization tool based on Hexaly Optimizer brought significant gains when it moved into production. The quality of the employee schedules and vehicle tours has improved, with gains of around 10% in terms of revenue per hour and distance traveled.

2 - Modeling Fairness in Covering Problems of Emergency Medical Service Location Planning

Isabel Wiemer, Jutta Geldermann

Emergency medical service (EMS) has to respond quickly and efficiently to all emergencies within a considered area. However, especially in areas with heterogeneous demand distribution, like urban, mixed and rural areas, the level of coverage can vary widely. To reduce inequalities in coverage, many approaches take into account fairness as model objective by explicitly addressing the coverage of the worst-covered area. Thereby, the coverage levels of the second, third etc. worst-covered areas are not directly addressed. Therefore, we propose to maximize the average expected coverage of the set p of worst-covered areas. Our model explicitly considers the second, third etc. worst-covered area and aims to improve not only the coverage level of the worst-covered area, but the average coverage level of the set p of worst-covered areas. Our fairness objective's applicability is analyzed at hand of a real-world case study for the city of Duisburg (Germany). We examine different sets p of worst-covered areas to analyze the influence on the individual coverage levels of the different areas. First results show that the proposed fairness objective can improve the average coverage of the set p of worst-covered areas in EMS location planning context. At the same time, computational complexity of our model is low enough to maintain solution quality.

3 - Optimal decision control for a mixed fleet emergency medical services system with dispatch protocols for ALS ambulances using semi-Markov decision processes.

Stelios Koukoumialos, Giannis Kechagias, Alexandros Diamantidis, Theodosios Dimitrakos

A mathematical model for the analysis of an Emergency Medical Service (EMS) system with a specific number of advanced life support ambulances (ALS) and a specific number of basic life support ambulances (BLS) is presented in this work. The system admits incoming emergency calls which are divided into two classes: (i) urgent, high-priority calls for which the patient's life is potentially at risk and (ii) less urgent, low-priority calls. Advanced life support units can serve both calls, while basic life support units handle only low-priority calls. The system either serves the incoming calls or forwards them to other systems if there are not enough ambulances for serving. Under a suitable cost structure, the system is modeled using an appropriate Markov decision process in continuous time for which we seek a stationary policy that minimizes a predefined optimality criterion for vehicle mixes over a set of candidate ambulance fleets. Based on this formulation, it is possible to implement standard Markov decision algorithms, such as the standard value-iteration algorithm and the standard policy-iteration algorithm.

4 - Rendezvous Strategy for Emergency Logistics *Changle Song, David Levinson, Emily Moylan*

An essential aspect of Emergency Medical Services (EMS) is the effective allocation of ambulance resources, which can greatly influence patient outcomes. Key to this is the dispatch policy for ambulance deployment and the question of whether specialised ambulances, specifically designed for certain types of incidents, should be assigned to other types of emergencies when available. This research uses queuing models to represent the different dispatching policies and implements simulations to identify the most efficient policy for ambulance resource allocation that would yield optimal patient outcomes when using specialised vehicles. This study proposes a simulation framework and methodology that could be adapted to other geographical regions, thus offering a versatile tool for evaluating the potential benefits of

deploying specialised emergency vehicles. The model considers multiple types of emergency vehicles, the distribution of patient demand, and the EMS response process. The experimental results demonstrate that the deployment of advanced specialised ambulance vehicles can enhance the survival rates of emergency incidents, particularly those corresponding to the vehicles' intended function.

5 - Ambulance routing problem for emergency medical services

Issam Nouaouri, Hamid Allaoui

In recent years, and particularly following the Covid 19 pandemic, an increase in the number of patients in hospital has been noted. Medical transportation is essential for an effective and efficient healthcare system. Demand continues to grow with the increase in needs from medicine (city or country medicine) and healthcare structures. The costs linked to medical transport are constantly increasing. Also, during an emergency, transport can be a determining factor in saving human lives. In this context, the problem is to reduce cost with better regulation and efficient use of resources, while guaranteeing the quality of service to patients. Medical transportation problem is known in the literature as the Ambulance Routing Problem (ARP). To deal with this problem, we propose two approaches: a Mixed Linear Programming (MILP) and a meta-heuristics based on evolutionary and local search algorithms. The goal is to minimize patient waiting time, travel time, and travel cost. This involves developing a decision support tool for planning and optimizing ambulance routes. The first results of the experimental study show that the proposed approaches improve the objective function.

1 - Empirical studies for comparing interactive multiobjective optimization methods with human participants

Giovanni Misitano, Bekir Afsar, Johanna Silvennoinen, Ana Belen Ruiz, Francisco Ruiz, Kaisa Miettinen

Applying interactive multiobjective optimization (MOO) methods necessitates preference information from a decision maker (DM). Because of the active role of the DM, comparison of interactive methods must be planned carefully. Previous comparisons have been rare and irreproducible. We have developed a new, reproducible experimental design to compare interactive MOO methods with human participants. Our design utilizes a novel questionnaire, which can measure the cognitive load experienced by DMs, their satisfaction with the solution process and the solution finally obtained. We can also measure the methods' ability to reflect preferences and responsiveness to changes in the preferences. Moreover, we have developed a web-based user interface to allow participants to access and utilize interactive methods, and to answer the questionnaire interactively. Our design enables a transparent and reproducible comparison of interactive MOO methods.

2 - Random Preference Model

Moha Ghaderi, Kamel Jedidi, Milosz Kadzinski

Modeling preferences from observed choices is a pivotal theme in mainstream economics and decision theory with expansive applications in policymaking, marketing, and transportation. The standard approach in modeling preferences is to attach utility scores to the choice options consistent with the order defined by the preferences. Nevertheless, the utility scores are merely artifacts or mediums to represent

preferences, whereas preferences are the underlying construct generating choices. We aim to develop a framework faithful exactly to this view. Our model takes preferences as the central primitive. Preferences generate choice data and are represented by analytically convenient mediums called utility functions. We argue that contrary to our approach, defining preferences in terms of utilities and choices can pose severe challenges for nonparametrically inferring the underlying choice process. To address this shortcoming, we model preferences directly by a probability distribution over the set of strict linear orderings of alternatives instead of an underlying utility. We build on the theoretical ground of the random preference literature and use the distributionally robust nonparametric approach to minimize the specification and distributional assumptions required to derive robust conclusions. We address the computational challenges and demonstrate the applicability of our model through an empirical application to a conjoint setting.

3 - Evaluating actor behavior under uncertainty for participatory interventions

Ruben Akse

Multi-actor decision-making for transport innovations is complex, among others because of the uncertainty experienced by decision-makers about other actors' behavior. Reducing this uncertainty by gathering more knowledge is insufficient and often impossible. Therefore, interventions are needed that assist actors in stimulating adaptive and collaborative thinking. The research gap this study aims to address is how to assess actor behavior under uncertainty for participatory interventions. Previous studies show that actors in the transport domain experience more uncertainty about governance than system problems regarding technology and sustainability. Also, actors treat long-term uncertainties as short-term risks, and are focused on reducing the latter by project management strategies. In this study, we intend to validate these findings, and how this is conditioned by individual and organizational variables. A stated preference survey has been performed in which mobility professionals had to indicate their strategy in alternative transport innovation scenarios. Scenarios include governance, system, long- and short-term uncertainties. Respondents are asked to state their preference for a strategy, given the scenario: Stop the project, do a risk-assessment for their own organization, or explore the possibilities collaboratively. The results of this study provide a theoretical basis for actor behavior under uncertainty and are illustrated by an intervention in a serious game.

4 - Multiple conflicting objectives cause psychological burden on decision-makers and lowers decision quality

Jyrki Wallenius, Matias Kivikangas, Eeva Vilkkumaa, Julian Blank, Ville Harjunen, Pekka Malo, Kalyanmoy Deb, Niklas Ravaja

Practical planning and decision-making problems are often better and more accurately formulated with multiple conflicting objectives rather than a single objective. This study investigates a situation relevant for Multiple Criteria Decision Making (MCDM) as well as Evolutionary Multi-objective Optimization (EMO), where the decision-maker needs to make a series of choices between nondominated options characterized by multiple objectives (criteria, attributes, dimensions). The cognitive capacity of humans is limited, which leads to "cognitive burden" that influences human decision-makers' decisions. We measure how different levels of decision difficulty - the number of decision-making dimensions (attributes, criteria, objectives) - influence the cognitive burden in a laboratory study, and the impacts that this burden has on the decision-makers' behavior and the quality of their decisions. We use psychophysiological, behavioral, and self-report methods. Our results suggest that a higher number of decision-making dimensions (i) increases cognitive burden significantly, (ii) leads to adopting satisficing strategies in which only a limited number of dimensions is considered, and (iii) decreases decision quality.

1 - Modeling a harvest planning and scheduling problem in a hierarchical agrifood supply chain by bilevel programming

Victor M. Alborno

The contribution addresses a harvest planning problem in the context of a hierarchical agrifood supply chain, which integrates the definition of management zones for harvesting, the harvest scheduling problem and the coordination between the producer and the wholesaler. The problem is represented through bilevel programming models that allow the representation of the hierarchy between the producer (leader) and a wholesaler (follower). The producer plans and schedules the harvest of the different homogeneous management zones into the resulting partition of the farm and the production levels to be offered to each wholesaler, while the wholesaler decides the quantity of product to be purchased to satisfy the demand requirements. First of all, a mixed-integer bilevel program is proposed and solved alternatively using an algorithmic strategy based on the Benders decomposition method. Then, a stochastic bilevel program is also proposed for representing the uncertainty in future crop yields, prices, and demands, using a finite set of scenarios. The bilevel optimization models considered are reformulated into mixed-integer linear programs using the Karush-Kuhn-Tucker conditions and replacing the nonlinear complementary constraints by the big-M method. The models were applied in a Case Study for selective harvesting of grapes with data collected from a farm. The results obtained when solving a set of instances highlight the importance of the problem and the proposed methodology.

2 - Model-Based Optimization of Irrigation Water Allocation at the Watershed Scale

Noam Ouzana, Isaya Kisekka, Raphael Linker

Efficient water resource management in agricultural contexts is a major challenge. The present study focuses on the allocation of irrigation water between competing crops at a watershed scale. The first step of the optimization process includes the division of the area into response units, which assists in maintaining complex modeling with high spatial resolution, while reducing the computation times by avoiding calculations over every pixel. This is done using the well-established SWAT+ model, which predicts, among others, the impact of different management decisions on fields within the watershed. A model-based, multi-objective optimization approach, which seeks to maximize the yield and to minimize the irrigation in each unit, is implemented on each of the response units. A curve is then fitted to the resulting Pareto front providing an estimate of the unit water productivity function (WPF). The estimated WPFs are then used for determining the amount of water that should be allocated to each crop for the next irrigation season through a single-objective optimization process, where the goal is maximizing the economic profit. This optimization framework is applied to the San Joaquin watershed, which is predominantly occupied by agriculture fields and orchards, and relies heavily on irrigation.

3 - Robust Network-based Optimization for Multi-Period Fuel Treatment

Tomas Lagos, Nam Ho-Nguyen, Dmytro Matsypura, Oleg Prokopyev

Wildfires pose grave risks to human life, health, and infrastructure. To address these challenges, proactive fuel treatment strategies are crucial before each fire season. However, managing fuel treatment resources in south-east Australia becomes problematic due to species protection and forest maturity considerations. Existing models to tackle the multi-period problem consider inaccurate approximations based on estimated

parameters in order to design treatment plan schedules. Our study extends previous work and introduces a robust modeling approach for devising multi-year treatment strategies. Initially, we introduce a new, more efficient formulation to solve the deterministic counterpart of the problem, which is then extended to account for a given fixed noise that surges the amount of fuel load due to uncertainties in vegetation growth and treatment effect. We then expand this formulation to accommodate a fixed noise factor, representing uncertainties in vegetation growth and treatment effects. Subsequently, we adapt the model to a robust setting, allowing "nature" to select values from a decision-dependent uncertainty set. Our polynomial size robust mixed-integer optimization model incorporates worst-case scenarios from the planner's objective perspective of fuel growth and treatment effects, offering adjustable uncertainty levels. Moreover, our modeling approach provides flexibility for planners, enabling them to minimize the total fuel load or optimize network connect

4 - Optimizing Winery Production Transfers using a Mixed-Integer Model to Reduce Water and Energy Consumption

Francisca Rosell

This work focuses on tanks' wine transfers in a winery that are part of the production process of the wine before being bottled. During peak production periods, the winery may face a shortage of available tanks, resulting in unnecessary transfers and increased water usage for tank cleaning as well as higher energy consumption. To address this issue, a mixed integer optimization model has been developed to reduce water and energy consumption by making only the necessary movements, using the minimum number of tanks, and covering the shortest distance. The model is based on three critical elements: the production planning, the tanks, and the route for the wine production. The production planning defines what and when must be produced and the initial mixtures for each class of wine. The ordered sequence of stages to produce each type of wine defines a route. Each stage requires tanks to keep the source and the resulting product. The model ensures each product follows the defined order, using only the necessary tanks and covering the shortest distance. The non-overlapping of tanks is guaranteed, which can be reused once they are empty and clean. The duration of each operation is considered, including transfer time and cleaning after each use. Furthermore, the model ensures that tanks are filled up following wine requirements at each stage to guarantee the quality of the final product. The application of the model is demonstrated in a variety of realistic examples.

1 - Exploring the decision space to support the decision maker's reflection on strong or weak urban sustainability

Beatrice Mecca, Matteo Brunelli, Isabella Lami

The sustainable development of cities requires a focus on what is essential for the global ecosystems and economies. In this sense, it may be useful to introduce the concept of weak and strong sustainability (WS and SS) in urban contexts. Indeed, it is well known that environmental problems have a local origin, even though they manifest themselves globally. The concept of WS and SS involves a different consideration of the relationship between natural and human capital, which can be interpreted in different ways of translating sustainability to decision-making processes. In evaluation, the choice towards

one type of sustainability entails a different process of aggregating indicators: this element is identified as the one to be paid the most attention when conducting an evaluation towards SS. To stimulate the decision-makers reflection on which type of sustainability is supporting his/her urban transformation, this paper intends to contribute to articulate the reasoning and explication of the negative and positive elements of the project alternatives. Specifically, we employ the p-ary Choquet integral to represent various strategies across distinct regions of the decision space. To manage the extensive preference information that needs to be gathered, we adopt a parsimonious elicitation method introduced by Labreuche and Grabisch, ensuring the problem remains manageable. The advantages of this method are illustrated through the application to an urban case study.

2 - System maps to foster a multi-perspective view on the energy transition

Yvonne Beck

Modelling, quantitative or qualitative, is part of many study programs. However, transferring trained methodology to application may depend on skills to communicate models in a multi-perspective context. Based on multi-perspectivity in technology (Ropohl 2009), the study investigates how system mapping with causal loop diagrams supports a multi-perspective view on the energy transition. The study was conducted with five study groups and analysed building a typology based on qualitative content analysis (Kuckartz 2018). Five types were identified along the typology's axes "modelling preconceptions" and "linkage of perspectives": The two central types group participants, who, despite lower modelling experience, connected several perspectives using the mapping methodology. Communicating the models to peers enhanced their learning. The "explorative type" transcended perspectives but did not follow the mapping approach closely, while the "trained methodologist" linked qualitative to quantitative modelling, remaining in a preferred perspective. The "multi-learner" was able to holistically integrate modelling approaches and perspectives. The findings suggest that short sessions combining soft model building techniques with phases of interaction may be suitable to develop a common-sense understanding for complex questions e.g. concerning sustainability transitions. Possible applications for interdisciplinary stakeholder dialogues are presented.

3 - Crafting Consensus: A conceptual model for enhancing urban infrastructure maintenance decisions

Roya Meydani, John Leander

Infrastructure owners face challenges in maintenance decision-making due to the process's multidisciplinary nature, spanning mathematics to cognitive science. This study optimizes maintenance for complex infrastructure systems, specifically in scenarios where a single primary owner must consider the preferences and requisites of multiple stakeholders. We propose a generic conceptual model facilitating shared views, eliciting objectives early, and aligning agendas with desired outcomes. It offers valuable guidance for decision modelers, reinforced by case studies. The decision-making process in infrastructure management varies based on industry standards, organization, and public expectations. Evolving approaches recognize infrastructure as part of a complex process, intensifying challenges such as multi-disciplinary issues and stakeholder conflicts. In this matter, effective management involves understanding uncertainty, navigating complex systems, and establishing optimal solutions. Moreover, social complexity emerges when stakeholders hinder collective inquiry due to singular problem perceptions. In response, decision agents play crucial roles, facilitating consensus and commitment while promoting shared understanding and restructuring education for a complexity mindset.

1 - Decommissioning and Conversion Optimization for Automated Natural Gas Distribution Grid Planning

Moritz Franz, Florian Hirschmann, Lars-Peter Lauen, Khalil Ben Safta, Anton Bergmann

Due to the energy transition towards renewables, renewable alternatives will likely replace natural gas-based heating in the medium term. Such alternatives include renewable methane and hydrogen as well as heat pumps. Currently, the expectation is that natural gas distribution grids will therefore face declining usage in many areas.

To consider this development in automated energy grid-planning approaches, an existing, pandapower-based power grid expansion algorithm is extended to natural gas networks using pandapipes and enhanced to also cover partial decommissioning of natural gas pipelines.

The decline of gas consumers in the gas grid reduces the flow rate in pipelines in some areas, possibly leading to violations of the network operational constraints while also rendering a number of assets redundant. The algorithm uses Iterated Local Search with either Hill Climbing or Late Acceptance Hill Climbing and cures violations by shutting down or adding selected pipelines or pressure controller to the grid model. If a pipe shut down results in unsupplied sinks, the algorithm uses the Delauney Triangulation to generate potential new paths to reconnect the sink.

A special optimization problem occurs if numerous natural gas consumers intend to switch to hydrogen instead. In this case, the algorithm's task is to design a hydrogen network while leveraging existing pipelines through conversion and observing all relevant operational restrictions.

2 - Modeling of a Hydrogen Economy in Integrated Assessment Models: A Review

Olivier Bahn, Kamyar Amirmoeini, Sara Ghaboulouian Zare, Normand Mousseau, Najmeh Neshat, Martin Trépanier

Within the needed global energy transition, hydrogen presents a potential avenue for achieving deep decarbonization. The expanding role of hydrogen in the global energy landscape is underscored by governmental interest. Recently, new national strategies have been adopted, taking the total number of countries with hydrogen strategies to 41 countries in 2022. To assess the decarbonization potential of a hydrogen economy, one may use an integrated assessment approach, a comprehensive framework that incorporates insights across diverse sectors like energy, land use, and the broader economy, along with their associated greenhouse gas emissions. Integrated assessment models (IAM) are mathematical tools to conduct an integrated assessment. This presentation proposes a survey of 12 distinct family of IAM from 50 different studies, to assess the potential of a hydrogen economy for different scenarios developed within the IPCC Sixth Assessment Report WGIII. This presentation also reports on our ongoing efforts at GERAD to model hydrogen production pathways in our AD-MERGE integrated assessment model.

3 - Optimal operation of a grid connected electrolyzer and greenhouse gases emission accounting

Giulia Montanari, Nicolas Campion

This analysis utilizes a deterministic optimization model to determine the optimal operational production of electrolytic hydrogen. The objective is to compare different operational strategies for electrolyzers considering electricity prices, subsidies for certified renewable hydrogen production, and regulatory constraints on GHG emissions. Using electricity grid data from Northern Italy, hourly grid emission factors are calculated through various methodologies, including European

regulations for Renewable Fuels of Non-Biological Origin production, the IPCC approach, and short-run marginal emission factors. Different emission accounting methods, such as Scope 2 and 3 from the Greenhouse Gas Protocol and the EU methodology are also considered. The comparison between different emission accounting methods shows that emissions calculated with Scope 3 are around 38% higher than those calculated considering Scope 2, and time-varying emissions calculations show a significant difference from yearly average methods, particularly when applied to a flexible load. The study highlights the temporal alignment of low prices and high emission factors; therefore, emission accounting methodologies that promote hydrogen production during low-price hours do not meet the need for GHG emission reduction. The findings indicate that different accounting methods impact the optimal operational behaviour of the electrolyzer and suggest the need of different strategies to reduce emissions.

4 - Quantifying the potential of curtailed electricity to produce green hydrogen

Alissa Ganter, Paolo Gabrielli, Tyler H Ruggles, Giovanni Sansavini, Ken Caldeira

Hydrogen produced with low-carbon emissions plays a central role in European decarbonization strategies. Scaling up renewable hydrogen production is envisioned to speed up the energy system transition and reduce dependency on fossil fuel imports. To facilitate this scale-up, the European Union introduced guidelines outlining the conditions under which hydrogen is considered a renewable fuel. These guidelines specify that electrolyzers should only be powered by grid electricity during hours with excess renewables, or by electricity from dedicated renewable assets. With increasing shares of renewables in Europe, in recent years, about 85-100 TWh of renewable electricity has been curtailed annually. In this study, we use a linear optimization model to determine the optimal capacity and operation of electrolyzers for varying hydrogen prices and investigate the untapped potential of utilizing this excess renewable electricity for hydrogen production. While the option to deploy battery storage is included to store otherwise curtailed power for later use, it is not deployed in any scenarios considered due to high up-front investment costs. We show that by utilizing otherwise curtailed renewable electricity, about 30% of today's European hydrogen demands from chemical industry and refineries could be met. The highest potentials are found in Germany, Denmark, and the Netherlands, where electrolytic hydrogen could displace over 60% of existing fossil hydrogen production.

1 - Peak prediction of pediatric hospitalizations due to respiratory diseases

Gloria Henríquez Díaz, Samuel Marin-Navarro

INTRODUCTION In Chile, every year in fall and winter, respiratory diseases increase in pediatric population (due to different factors) and this produces an increase in the number of hospitalizations, sometimes collapsing the health system. To anticipate, a system has been created to predict when the peak will be.

METHOD Data from Luis Calvo Mackenna Hospital were obtained from the open access database DEIS of the Ministry of Health. The created system was used to predict the peak date of pediatric hospitalizations from 2017 to 2023, except 2020 and 2021 due to the pandemic. The curve produced were smoothed by moving averages. As the curve

ascends, alerts created with machine learning begin to appear. The model was tested using antecedents from 2 to 7 previous years.

RESULTS Tests performed with 7 and 6 years of historical data had 100% results within the prediction interval (RMSE = 7.0 with respect to the exact day), while with 5 and 4 years were 67% (RMSE = 10.2) and 50% (RMSE = 11.3), respectively. Finally, with 3 years it was 20% (RMSE = 11.4) and with 2 it was 0% (RMSE = 12.6). In all cases, the prediction was approximately one month in advance.

CONCLUSIONS The system created has promising results if sufficient historical data is added to train the model. A future challenge is to adjust it for other pediatric hospitals.

ACKNOWLEDGMENTS This work was funded by the ANID FONDEF IDeA I+D 2023 ID23110423.

2 - Predicting delayed discharge from hospitals: A Decision support system using machine learning

Majid Taghavi, Mahsa Pahlevani, Peter Vanberkel

The increasing demand for healthcare services poses significant challenges in effectively managing patient flow, particularly concerning patients classified as Alternative Level of Care (ALC). These patients, although no longer in need of acute care, often encounter obstacles to discharge and cause several issues such as hospital overcrowding and compromised health outcomes. This study uses administrative health data from Canadian hospitals and proposes using machine learning models to identify potential ALC patients and estimate their hospital length of stay as early as their admission time. The findings show the efficacy of the eXtreme Gradient Boosting algorithm in accurately predicting potential ALC patients, while the Random Forest regression model surpasses others in forecasting the length of stay for ALC patients. To understand how the predictions are made from the features of the dataset, the Shapley values were analyzed and used to identify the most important features of the dataset and their impact on machine learning outcomes. Using the most important features, two sets of user-friendly and easy-to-follow guidelines were developed for the hospital staff to proactively identify the ALC patients and estimate their length of stay, and mitigate the patient flow challenges posed by the ALC patients. Hospitals can use such decision-making tools to optimize resource allocation, enhance operational efficiency, and ultimately improve patient care outcomes.

3 - Balancing Cost and Profit in the Public Sector Vaccine Market

Banafsheh Behzad

This study addresses how the government can ensure the cost-effective procurement of vaccines from private manufacturers. We combine optimization and game theoretic techniques to address cost-effective immunization in the United States. Our optimization model from the government's perspective minimizes negotiated government costs, while ensuring adequate national vaccination levels, linking dynamics in public and private sectors and incorporating competitive manufacturer behavior. The optimization model embeds an extant game theoretic price model to capture competitive interactions among manufacturers in the private sector. The model is applied to two different case studies of the US pediatric vaccine market and the COVID-19 vaccine market. The results indicate that markets are at lower risk when high capacity manufacturers have moderate target profits, especially in cases of high demand and asymmetry. Our model can help restabilize a market that experiences a vaccine shortage. We also underline scenarios in which the government may be able to prevent monopolies through financial incentives to manufacturers. The results support a paradigm shift from annual contracts to ongoing negotiations, which would enable the government to exercise control over high-risk markets. Our study demonstrates an analytical approach for managerial government officials to influence vaccine prices via the procurement of public-sector goods.

1 - Educational Admissions Transformed: Navigating the Future with Intelligent Screening

Pin-Rui Hwang

Integrating intelligent screening technologies into educational admissions systems fundamentally transforms the role of educators in selecting candidates. By employing advanced AI-based techniques, this system enhances the decision-making capabilities of educators in the candidate selection process. The system assists educators in identifying promising candidates through the analysis of applicant data, including academic achievements, extracurricular activities, and personal statements. The theoretical foundation is rooted in predictive analytics, which assesses the content presented in applicants' documents and their compatibility with the program's development to estimate candidates' suitability and potential success. This adjustment more accurately reflects the review and evaluation of student data in the university admissions process, particularly regarding the alignment of students' demonstrated content with the objectives of their chosen department.

2 - The Role of the Multi-dimensional Learning Environment in the Context of Responsible Management Education

Johanna Oster

The need for a socio-ecological transformation of society is being emphasised in different contexts. Tomorrow's business leaders will play a key role in this transformation. Therefore the call for more Responsible Management Education (RME) is becoming steadily louder. In response, the United Nations-backed Principles for Responsible Management Education (PRME) initiative was founded, aiming to provide future leaders with the skills they need to contribute to a sustainable development. Three curricular dimensions influence, whether students gain these skills: the formal, the informal and the hidden curriculum. Aims of RME can only be reached if all three dimensions are aligned. However, currently scholars pay little attention to the hidden and informal curriculum. This research aims to generate knowledge about the hidden curriculum. Moreover, connections between formal and hidden curricula shall be researched. The hidden curriculum will be examined through questionnaires and group discussions, including stimulated recalls. The formal curriculum will be raised through a documentary analysis. Discussions and documents will be evaluated with qualitative content analysis. The results will presumably provide profound knowledge concerning the interaction mechanisms of formal and hidden curricula. The outcome can help researchers develop RME implementation models. Moreover, this knowledge can support lecturers in questioning and improving RME in their institutions.

3 - Towards Equity in Teaching Management Science

Ken Murphy

Student outcomes in an undergraduate management science course are hypothesized to depend on prior preparation and student engagement. A predictive model is presented that combines these factors using data gathered from large, online course sections of business students. The results help to inform instructors of actions to take to create equity of opportunity in the STEM classroom.

4 - Nordic Project Funding as a Means to Create Impact with Your Research

Lise Nielson

During the talk, I will present both the conditions we have to take into account in selecting call topics for our funding effort, and present some of our funding opportunities, such as the mobility and network programme for PhD students and researchers, our Hydrogen Valleys programme and our Nordic Grand Solutions programme (Technology agnostic, must meet impact goals of importance for the green transition).

1 - A Patient-Centered Hospital Procurement of Physician Preferred Implants

Renato de Matta

We study the procurement of physician-preferred implants where both the hospital and patient surplus are considered and optimized. For better flexibility, we introduce the use of alternate devices instead of preferred ones. Considering alternate implants allows for improving the hospital surplus through larger revenues and volume discounts, although it implies an additional cost to cross train physicians who may need to use implants and associated surgical procedures they are less familiar with. The problem is NP-hard. We propose two heuristic procedures for quickly finding nearly optimal solutions and for estimating the optimality bound. We demonstrated results of a series of experiments where we considered different scenarios corresponding to several patient demand distributions across patient-types and emphasized the benefits of alternate implants and physician cross-training. Using patient-reported costs and total hip replacement outcomes from the medical literature in the experiments, we show that the increased flexibility physicians acquire from cross-training: (1) Improves patient outcomes; (2) Improves the hospital's financial performance by increasing hospital revenues and cost savings from volume discounts when larger orders of certain medical devices are placed; (3) Improves patient and physician satisfaction; (4) Reduces the negative impact of demand uncertainty on a hospital's financial performance.

2 - Selection and prioritisation of medical devices for HTA evaluation: Towards a socio-technical framework based on multiple criteria decision analysis

Ana Vieira, João Pimenta, Lilite Loição, Helena Monteiro

Given the diversity and rapid pace of innovation in the medical device (MD) industry, there is an increasing need for Health Technology Assessment (HTA) agencies to prioritise which MDs to evaluate. The Portuguese HTA agency, INFARMED, National Authority of Medicines and Health Products, I.P., intends to develop a socio-technical framework to address such a challenge. Taking a step towards this goal, the present study develops an approach for structuring a multiple criteria decision analysis (MCDA) model to measure the value of MD assessments. More concretely, it arrives at a robust value tree that represents the relevant value dimensions to consider when prioritising MDs for HTA evaluation at INFARMED. The proposed methodological approach follows a top-down ("value-focused thinking") approach, entailing a systematic literature review and social methods, such as a web survey and a workshop. Causal mapping, as a powerful visual tool capable of supporting structuring tasks, was applied as an intermediary method to build the final value tree. The resulting tree is structured into three levels, comprising criteria and attributes within two domains - disease-related and device-related dimensions. Looking forward to operationalising this structure in the future, selected MCDA techniques are discussed. All in all, the present study provides a sound operational basis for the framework sought by INFARMED, with potential relevance for future studies on HTA priority-setting.

3 - Site selection problems for clinical trial supply chains

Anh Ninh, Yunhong Bao, Daniel Mcgibney, Tuan Nguyen

Recruiting candidates globally and across multiple sites in different geographic regions is necessary to speed up the enrollment of clinical trials. While patient enrollment can benefit from this globalization, initiating clinical trials has become much more complicated. In the start-up stage, the sites must be selected out of a set of potential candidates around the globe based on the specifics of those clinical trials, such as protocols, operational costs, and recruitment deadlines. Sites in one region can be very distinct from sites in another area. Yet, a common mistake in selecting sites is to rely on too little knowledge or subjective data. Poor selection decisions can lead to study delays and prolong the time to market for life-saving treatments. Thus, we propose a framework to aid the decision-making in global site selection problem. To ensure that our framework accurately captures the uncertainty in recruitment time, we adopt a risk-based constraint that accounts for random patient enrollment. The extensive computational studies help quantify significant time-cost trade-offs as a potential solution to control the costs of conducting a trial.

4 - Supporting long-term decision making at regional level through modelling long-term changes in population health state and associated healthcare resource usage

Christos Vasilakis, Zehra Önen-Dumlu, Luke Shaw, Richard Wood

Decisions around medium and long-term allocation of healthcare resources are fraught with challenges arising from the inherent uncertainties in population growth as well as developments in the economy, society and technology. Against this background, health and care planners are constantly facing challenges on how to allocate healthcare resources with limited budget. The aim of this paper is to describe the development and early use of an innovative mathematical model and accompanying tool that captures the likely impact of long-term changes in a regional population and associated healthcare resource requirements. The modelling tool works in two stages: first, it derives 20-year population projections based on a Markov chain; second, it calculates healthcare activity and related costs for same time horizon. Population projections are based on segmentation of the population with respect to the Cambridge Multimorbidity Score derived from a state-of-the-art system wide dataset that provides patient-level linkable data for the entire population of a region in England of about 1 million people. Our innovative model and tool, which is already informing decisions in the collaborating health care system, offers planning support by generating long-term population projections as well as provides capacity for running scenarios that flex the 'do nothing' (baseline) scenario by considering various mitigations.

climate change including heat and flood while they continue to produce greenhouse gases that contribute to climate change. A city is composed of diverse districts. While urban structure, land use and form matter at the city or regional scale, physical environment of districts should be improved to make them inclusive, safe, resilient and sustainable. The district scale is said to be an appropriate scale for climate actions as it is small enough to innovate quickly and large enough to have a significant impact. Participatory urban design methodology is needed at the district scale as there are various stakeholders that shape the physical environment composed of buildings, open spaces and public spaces. Based on the history of participatory urban design, or Machizukuri in Japan, we are starting to incorporate digital tools such as thermal simulation and carbon mapping into stakeholder workshops to initiate place-based climate change actions. Both tools are developed on a publicly available three-dimensional urban model. We will present several cases of participatory urban design practices in Japan using these tools and discuss about the achievements and issues.

2 - Optimal Placement of Nature Based Solutions in Urban Greening

Diego Maria Pinto, Davide Donato Russo, Antonio M. Sudoso

This paper addresses the strategic placement of nature-based solutions (NBSs) to enhance sustainability and resilience in cities. Leveraging Operations Research (OR) tools and convolution theory, we propose a comprehensive and flexible approach to maximize the benefits of urban green infrastructure while ensuring equitable distribution across urban areas. Our formulation integrates multiple variables, benefits, and constraints, including fairness considerations, to identify optimal locations of NBSs such as parks, green walls, green roofs, and tree plantings. Through several case study analyses, we demonstrate the effectiveness of our approach in improving environmental and social indicators. This research contributes to advancing the understanding and implementation of NBSs in urban planning, offering valuable insights and decision support for re-designing resilient and equitable cities.

3 - A Framework to Identify and Prioritize Key Performance Indicators: Assessment of the Effectiveness of Inclusive Climate Actions for Nature-based Solutions

Virginia Pellerrey, Sara Torabi

Nature-based Solutions (NbS) are increasingly acknowledged as vital strategies against climate change. However, citizens and ecosystems benefit differently from NbS. To account for NbS trade-offs, theory and practice have embraced Inclusive Climate Actions (ICAs) that simultaneously tackle climate change and urban inequalities. Currently there is a notable gap in the assessment of environmental, economic, and social implications of ICAs for NbS. This research develops an evaluation and monitoring (E&M) framework to identify Key Performance Indicators (KPIs) for evaluating the effectiveness of ICAs for NbS. The methodology is structured in three phases: identification, refinement, and prioritization. This approach integrates quantitative and qualitative techniques and involves stakeholders in the process. A set of 13 KPIs is proposed. These results can be further enhanced by engaging local stakeholders to select supporting indicators tailored to address contextual challenges. The E&M framework assesses the effectiveness of completed or ongoing projects, or evaluates future scenarios. This step serves for empirical assessment in five European cities, and for the design and planning of future scenarios in five Urban Living Labs. Results will help cities to implement ICAs that incorporate fairness and distribute NbS impacts equitably. This study is part of the DUT project GREEN-INC, growing effective and equitable nature-based solutions through inclusive climate actions.

4 - Social impact assessment using ES through socio-ecological system dynamics digital simulation

Asef Ayatollahi, Eugenio Morello

Social impact assessment (SIA) of re-naturing measures in urban areas offers an exclusive perspective on complex interactions and trade-offs between humans and nature. Despite advancements in methodologies for short-term assessment, long-term assessments, and evaluations still require a concrete framework. The main challenges in long-term SIA procedures are the high volume of complexities and interconnectivity of interaction components and difficulties in citizens' engagements. Focusing on these issues by utilizing digital platforms, this research proposes a long-term SIA procedure based on the system dynamics

1 - Participatory Urban Design Methodology for Climate Actions at the District Scale: Thermal Simulation and Carbon Mapping

Akito Murayama, Junya Yamasaki, Takahiro Yoshida, Ryoichi Nitana, Rikutarō Manabe

Implementation of climate change mitigation and adaptation measures are urgently needed in cities as they experience severe impacts from

(SD) framework and co-monitored parameters to understand the value of re-naturing measures and biodiversity in urban areas. A systematic review collects direct and indirect social indicators, impacts, and factors of re-naturing through ecosystem services (ES). After contextualization at Giardino San Faustino, Milan, through consultation with actors, the results shape causal loop diagrams in the system dynamics framework. To comprehensively cover the extensivity of interactions and variable relations, the simulation tool of AnyLogic is used for full coverage of relations. This digital tool enables a complete construction of relations and simulates interactions for SIA in defined timelines reflecting limitations and advantages in each scenario. The results render a spectrum of interaction dynamics aiding decision-makers in better evaluating human and nature interactions.

1 - Machine Learning based surrogate models for large-scale sector-coupled energy systems

Tim Graulich, Marie Münster, Bissan Ghaddar, Rasmus Bramstoft

Surrogate modeling is a well-established field within engineering sciences, where computational simulation and optimization models are becoming increasingly complex. Instead of running costly high-fidelity models, surrogate models can provide accurate estimations, while reducing computation times. Currently, the energy system is becoming increasingly integrated across the energy sectors and vectors, leading to a growing demand for sector-coupled large-scale energy system models. At the same time higher shares of variable renewable energy sources require higher temporal and spatial resolutions when performing the energy system modeling. This development results in an increasing complexity of these models. One possible method to deal with this growing complexity is to build surrogate models representing a specific energy sector (e.g. hydrogen), which can then be coupled to another operational model (e.g. power system model). However, while surrogate models have been used for various applications in the energy domain, ranging from building energy performance simulation to power grid optimization, no surrogate models have been developed to represent large-scale sectoral energy system models. A big challenge of these model is the large number of input and output parameters. This talk will present ongoing research on how to use sensitivity analysis to reduce the models complexity for the surrogate model.

2 - A Quantile Neural Network Framework for Two-stage Stochastic Optimization: Application to Power Systems Operation

Antonio Alcántara, Carlos Ruiz, Calvin Tsay

Two-stage stochastic programming is a popular framework for optimization under uncertainty, where decision variables are split between first-stage decisions, and second-stage (or recourse) decisions, where the latter can be adjusted after uncertainty is realized. These problems are often formulated using Sample Average Approximation (SAA), where uncertainty is modeled as a finite set of scenarios, resulting in a large deterministic problem, i.e., where the model is repeated for each scenario. The resulting problems can be challenging to solve, and several decomposition approaches have been proposed. More recently, Patel et al. (2022) approximated the expected second-stage objective value for a set of scenarios using a neural network, which can then be embedded in the first-stage problem to produce good heuristic

solutions. In this work, we propose approximating the second-stage objective value with a quantile neural network, which can capture uncertainty and is not limited to expected-value optimization, e.g., to optimize the Conditional Value at Risk (CVaR). We discuss optimization formulations for embedding the quantile neural network and demonstrate the effectiveness of the proposed framework using several computational case studies including mixed-integer and nonlinear problems. Particularly, we test this novel methodology in relevant power systems' operation problems with high renewable energy penetration.

3 - Learning-Assisted Optimization for Transmission Switching

Salvador Pineda Morente, Juan Miguel Morales, M. Asuncion Jimenez-Cordero

We propose a novel learning procedure to assist in the solution of a well-known computationally difficult optimization problem in power systems: The Direct Current Optimal Transmission Switching (DC-OTS). This model consists in finding the configuration of the power network that results in the cheapest dispatch of the power generating units. The DC-OTS problem takes the form of a mixed-integer program, which is NP-hard in general. The proposed approach leverages known solutions to past instances of the DC-OTS problem to speed up the mixed-integer optimization of a new unseen model. Although it does not offer optimality guarantees, a series of numerical experiments run on a real-life power system dataset show that it features a very high success rate in identifying the optimal grid topology (especially when compared to alternative competing heuristics), while rendering remarkable speed-up factors.

4 - Learning-based State Estimation in Distribution Systems with Asynchronized Measurements

Jose Gomez de la Varga, Salvador Pineda Morente, Juan Miguel Morales, Álvaro Porras Cabrera

The task of state estimation in distribution systems faces a major challenge due to the integration of different measurements with multiple reporting rates and asynchronization. As a result, distribution power systems are essentially unobservable in real time, indicating the existence of multiple states that result in identical values for the available measurements. Certain existing approaches utilize historical data to infer the relationship between real-time available measurements and the state. Other learning-based methods aim to estimate the measurements acquired with a delay, generating pseudo-measurements. Our paper presents a methodology that utilizes the outcome of an unobservable state estimator to exploit information on the joint probability distribution between real-time available measurements and delayed ones. Through numerical simulations conducted on a realistic electricity network with asynchronized measurements, the proposed procedure showcases superior performance compared to existing state forecasting approaches and those relying on inferred pseudo-measurements.

1 - A granular approach to optimal and fair patient placement in hospital emergency departments

Dessi Pachamanova, Maureen Canellas, Georgia Perakis, Omar Skali Lami, Asterios Tsiourvas

Prolonged emergency department (ED) length of stay (LOS) is associated with detrimental effects on patient care and quality, including increased mortality, increased risk of hospital-acquired infections, and disrupted patient flow. There is also evidence that certain groups of patients experience longer LOS based on their gender or race, especially with regard to the part of LOS that is attributable to waiting to be seen by a clinician. This work tackles the patient prioritization and placement aspects of ED operations with the goal of improving throughput and wait time in a fair, equitable way. We present a novel Mixed Integer Linear Programming predictive-prescriptive formulation that incorporates a breakdown of predicted patient ED LOS into actionable pieces and allows for a more granular model of ED operations. We show how to incorporate considerations for fairness and reformulate the MILP formulation into a compact and computationally tractable formulation that can be solved efficiently in real time. This work was conducted in collaboration with a large US academic medical center. Data from more than 40000 patient visits were used to shape and evaluate the models. We provide an interpretable metamodel trained on the complex model's recommendations in order to help with the operationalization of the algorithm. The method will be used by the hospital to improve patient flow and quality of care as well as to support more fair and consistent bed allocation decisions.

2 - An Ethical compass for Artificial Intelligence (AI) and Chat CPT for students' and universities

Ulrike Reisach

This abstract focusses on ethical concerns for students' usage of algorithms AI and Chat CPT in different nations, laws and decision making. Depending on care takers, universities and teachers', the usage of those novel tools is quite different. For example, students might (a) be able or not able to (mis)use the tools, (b) find or lack access to true or false information, (c) loss of intellectual property rights, whether they and their parents or teachers are aware or not aware. This causes a discussion on ethical issues along the previously mentioned stakeholders and their complex societal or economic backgrounds. Using cases from Generative AI which describes algorithms such as Chat GPT, we will see what ethical issues mean for the students and their care takers and other stakeholders: Students who have access, usually like Chat CPT (Version 3, they cannot afford level 4) and they use it and their results sound good, but also lowers their own creativity as well as their analytical and critical thinking. This sample shows ethical concerns across biases, cultural/individual identities, autonomy, social justice, safety and accountability. In a nutshell: The existence of novel tools allows well-to-do users or universities to access new content and achieve support for various purposes like writing, speaking, marketing, etc., while issues like inclusion/social cohesion might be left, while commercial tool providers benefit from new customers and revenue.

3 - AI ethics-in-the-making: a situated perspective

Sabine Amend

In focus is a smaller Software-as-a-Software (SaaS) enterprise that is pursuing AI-led innovation as a key strategy. Get a front-row view of leader decision-making and organizational behavior as this enterprise is operating in turbulent market conditions. How are AI ethics made during an industry-critical 6-month period (2023/24)?

A contemporary interpretation of Aristotelian phronesis - the ethics of "practical wisdom" - and an adaptive systems lens form the basis of inquiry into the situated action at this SaaS business: How are AI ethics included, excluded, centralized, or marginalized while the technological landscape changes rapidly? Drivers for decision-making, such as the tangle of stakeholder relationships, the evolving AI-based products themselves, leader mindsets, policies, reputation management, and design processes come into view.

The situated exploration is set in the context of broadly discussed AI ethics frameworks, such as the EU guidelines, UNESCO recommendations, and current academic research. Together, they outline a map of gaps and blind spots, as well as effective practices. This map informs a discussion of the opportunities and constraints for embedding greater AI-ethics "practical wisdom" into turbulent organizational life - and for strengthening positive trajectories with AI technologies.

Chair: Natalia Alguacil

1 - Dynamic Expansion Planning of a Commercial Virtual Power Plant through Coalition with Distributed Energy Resources considering Rival Competitors

Santiago Maiz, Raquel García-Bertrand, Luis Baringo

We consider a virtual power plant (VPP) that expands its capacity by forming a mid-term coalition with distributed energy resources (DERs) such as conventional and renewable power plants, as well as with energy storage systems and flexible demands. The VPP competes with rival VPPs to aggregate the DERs to its own portfolio. This problem is formulated as a three-stage stochastic bi-level model, where the expected profit of the VPP is maximized in the upper-level problem, while the lower-level problems deal with the decisions of each DER regarding the selection of VPP. In the first stage, the VPP manager places bids to secure each DER auction. The second stage involves decisions to determine the DER auctions, forming the VPP coalition and the procurement of power from the day-ahead market. Uncertainties in this stage include bid prices of rival VPPs and the minimum selling price of DERs. Finally, in the third stage, the expanded VPP determines its optimal operation and manages uncertainties related to renewable energy production levels and market prices. Variability of parameters such as market prices and renewable energy production levels (both solar and wind) is modeled using representative days generated by a clustering K-medoids method. The model incorporates Conditional Value-at-Risk (CVaR) as a risk metric. Through a case study using real data, it is demonstrated that weather conditions and electricity demand significantly influence the coalition formation.

2 - Strategic Planning for Transition to Next Generation Clean Energy Technologies using Stochastic Programming

Burak Kocuk, Neman Karimi

In recent years, the transition from fossil fuels to clean energy technologies has accelerated. Although this transition might bring environmental and economic benefits, it requires a long-term strategic plan due to the large investment costs involved. In addition, the uncertainties in the technical and economic development of next generation clean energy technologies should be included in this plan. Our research focuses on optimizing strategic plans for the transition to next generation clean energy technologies using stochastic programming. As a case study, we examine the Machine Replacement Problem under Technological Advances. Although it is common to periodically replace machines that completed their economic lifetimes, the exact times of replacement should be optimally determined. For example, in the short-term, it might seem beneficial to replace a conventional machine with an existing clean technology whereas in the long-term, it might be more beneficial to wait and replace it with a future technology that is currently evolving. We formulate this problem using multistage stochastic programming by creating technology advancement scenarios. We analyze the underlying problem structure and the computational complexity of deterministic and stochastic versions. We also present how to solve large-scale problems more efficiently. Finally, we discuss potential applications of our approach to real-life problems such as clean energy transitions for fleets and campuses.

3 - Coordinated Generation Expansion Planning for Transmission and Distribution Systems via ADMM

Natalia Alguacil, Nahid-Ur-Rahman Chowdhury, Gregorio Muñoz-Delgado, Javier Contreras

This work provides a practical algorithm for solving the generation expansion planning problem for both transmission and distribution systems. Conventional and wind-based generators are eligible to be installed under a set of scenarios that captures the uncertainty arising from different operating conditions, demand fluctuations and wind dynamics. Assuming there is one planner at the transmission level and distinct planners for each of the analyzed distribution systems, an optimal expansion plan for the whole power system is obtained. The resulting problem, which is formulated as an instance of scenario-based linear programming, is solved here in a coordinated but distributed fashion by using the Alternating Direction Method of Multipliers (ADMM). Unlike other works that also facilitate transmission and distribution planners' coordination, the proposed solution methodology not only guarantees the finite convergence to optimality but also the privacy of information related to each planner's assets. Privacy is achieved by solely exchanging information on the injections at the interface nodes among neighboring transmission and distribution systems. The algorithm's performance is tested on small- and medium-sized systems, revealing a reasonable tradeoff between solution quality and computation times for a practical setting.

4 - Enhancing electricity system robustness through the application of a new time series cluster algorithm

Leonie Sara Plaga, Valentin Bertsch

The ongoing evolution of climate change presents unprecedented challenges to electricity system performance and reliability, which are inherently sensitive to weather conditions affecting both energy demand and generation capacities. To aid decision-making in energy systems under climate change influence, energy system optimization models can be combined with climate model outcomes. As future climate development is highly uncertain, there are many different climate models and human greenhouse gas emission scenarios projecting the future. Thus, we propose a new time series clustering algorithm. This algorithm allows to incorporate various climate models and emission scenarios into energy system optimization while focusing on providing a robust solution, meaning that the amount of unmet demand is low no matter which climate scenario is realized. The algorithm operates by first splitting the time series into single days which are optimized individually. The investment results of the single days are then used to calculate the amount of unmet demand which occurs when the single-day investment decisions are used with the complete time series. This data informs the clustering process, prioritizing days with high unmet demand. Our results demonstrate that this new clustering algorithm can reduce unmet demand compared to traditional cluster algorithms like k-means. In further research we plan to compare our approach to traditional robust optimization approaches.

1 - Reverse Supply Chain in the Semiconductor Industry: Examining the Blockchain Implementation

Davoud Hosseinnzhad, Sara Saberi, Sahar Ebrahimi Bajgani, Fuminori Toyasaki, Cathal Heavey

In response to recent global fluctuations, companies are turning to reverse logistics to minimize waste and increase production capacity. Implementing a reverse supply chain (RSC) is not without challenges, including obtaining e-waste with the right quality, preventing fraud, and disposing of sensitive information securely. Counterfeit electronic

parts are a significant threat to the reliability and safety of electronic equipment, highlighting the need for traceable systems to prevent and detect fraudulent activities and protect consumers. Blockchain technology (BCT) offers several characteristics to address these issues while bringing several challenges. It embraces substantial investments, encompassing technological assets and the development of requisite infrastructure. Cultural and governance issues also influence the willingness of all supply chain parties to collaborate on BCT investment. To address these challenges, we model an evolutionary game to investigate the following research questions: how does parties' adoption tendency in the semiconductor industry evolve, considering technical cost, partners' collaboration, and the ultimate goal of achieving complete transparency through BCT adoption? What is the impact of external factors, including cryptocurrency fluctuations and evolving consumer behaviors, on parties' decision-making processes in RSC, particularly concerning their adoption or non-adoption of Blockchain technology?

2 - E-waste reverse logistics in India: Collaborative collection and processing

Aditya Prabhakar

One of the widely adopted practices for e-waste reverse logistics is the sealed bid process. In this process, the seller first invites quotations for selling a set of e-waste. The recyclers then send their bids/quotations in sealed envelopes which are opened only on the prescribed date. The recycler with the highest bid wins the contract. In the above process, a seller may sell a particular type of e-waste or a combination of different types of e-waste. However, the recycler may or may not have adequate infrastructure to process each type of e-waste offered by the seller. In such situations, the recycler may collaborate with another recycler(s) to ensure better efficiency and make a higher profit. However, there are various uncertainties faced by the recyclers in terms of the quantity, quality, recovery rate, procurement cost, transportation cost, and processing cost of the e-waste. This paper tries to address the uncertainty faced by the recycler in terms of the procurement cost during a sealed bid process. While deciding on whether to bid or not in a sealed bid process, the recycler faces a tradeoff between profit margin and the quantity of e-waste collection. A stochastic integer linear programming model is proposed that would help recyclers decide an optimal bidding price for a certain set of e-waste to maximize their profit. Further, this paper analyses the impact of a coalition and the capacity allocation on the profit shares of the partner firms.

3 - How do past repair experiences affect expectations about right-to-repair legislation?

Weihua Zhang, Marc Reimann, Sadaat Yawar, Ines Güsser-Fachbach

In today's consumer-driven society, the issue of product repairability and the Right-to-Repair (RTR) movement have seen significant attention and debate. As these RTR laws and regulations are very recent, there is no evidence of their impact on the desired issues associated with the repair. It is not even clear how well known RTR legislation is among the general public, and what consumers expect from such legislation. Those expectations and whether as well as how they are eventually satisfied will shape the effectiveness of the legislation. To provide a comprehensive insight into the factors influencing expectations of RTR legislation, we conducted focus group interviews and a quantitative online survey with participants from both Austria and the United Kingdom (UK). Our main finding is that (in general) past experiences only indirectly affect the expectations about RTR legislation, namely via repair intention. These results are surprisingly robust when we zoom into the different types of repair scenarios, DIY and use of a repair service. Finally, comparing Austria and the UK, the results are strikingly robust. This research contributes to the growing body of knowledge on the RTR legislation and its implications for consumer behaviour, sustainability, and public policy. Moreover, this study offers guidance for policy-makers and repair companies in understanding the factors that influence consumer expectations of RTR legislation.

Chair: Grit Walther

1 - Green supply network design with carbon tariffs and location-specific carbon policies

Jens Christian, Florian Sahling

Carbon policies are often limited to specific regions. Therefore, carbon leakage leads to the relocation of production to regions without carbon policies. To prevent carbon leakage, the European Commission recently adopted the Carbon Border Adjustment Mechanism. It imposes carbon tariffs on carbon emissions imported into regulated regions. We present a new mixed-integer model formulation for global and multi-period supply network design subject to carbon tariffs and location-specific carbon policies (SND-CT-CP). Consequently, locations differ in whether and how carbon policies are active at the respective location. Here, we include carbon tax, carbon cap-and-trade and carbon caps as location-specific carbon policies. In contrast, carbon tariffs are imposed on emissions imported from unregulated locations. As we propose a strategic planning problem with a long-term planning horizon, we include uncertainties in the SND-CT-CP. These uncertainties focus on stochastic carbon caps, which have a particular influence on the supply network design. Within the presented SND-CT-CP, we consider a four-layer supply network. Accordingly, the locations of manufacturing plants and distribution centers are planned. Suppliers are selected based on resilience considerations. In addition, the demand includes price-dependent levels. Thus, the objective of the SND-CT-CP is to generate a supply network configuration that maximizes the expected net present value.

2 - Bi-Objective Supply Chain Network Design with Transport Mode Selection

Eberhard Schmid

In Supply Chain Network Design (SCND), the decision maker's task is to decide upon locations for production or distribution facilities, product allocations to warehouses and factories, customer allocations and the choice of the transport modes. These decisions do not only have an impact on the economic performance of the supply chain but also on environmental indicators like the emission of CO₂. To account for trade-offs, multi criteria SCND-modelling approaches are discussed increasingly. In this paper, we will present a bi-objective SCND modelling approach which explicitly considers the selection of the mode of transport, as one possible lever in the reduction of CO₂. We model specific characteristics of transport modes, like the lead time and the shipment size and their influence on safety stock and cycle stocks. Through this, we are able to model trade-offs, which so far are not considered in the literature on multi criteria SCND-models. We describe a solution procedure, which includes the conversion into a mixed integer conic quadratic optimisation model, demonstrate the applicability within a case study and discuss computational and managerial insights. Further we give an outlook on the possible error supply chain decision makers can make, when ignoring those effects in the application of multi criteria SCND models.

3 - A stochastic mixed-integer programming approach to optimize a renewable fuel supply chain under uncertainty of renewable electricity supply

Mina Farajimiri, Jörn Meyer, Grit Walther

Addressing climate change requires the transportation sector to adopt renewable hydrocarbon fuels, particularly in aviation, maritime, and heavy-duty road transport, where electrification faces challenges. This transition necessitates the design of new production networks and supply chains, yet it faces uncertainties related to resources, technologies, and demand. It is vital to ensure that these renewable fuel supply

chains are flexible and robust to uncertainties, such as supply and demand fluctuations or technological changes. We explore the impact of uncertainty on the design of renewable fuel supply chains, focusing on the variable capacity factors of renewable energy sources and their influence on electricity supply. We propose a multi-stage stochastic programming approach to optimize the renewable fuel supply chain design, taking into account seasonal and geographical variations in resource availability. We aim to minimize the expected total system cost while accommodating the uncertainty in the capacity factor of renewable electricity which will affect its supply. Scenario generation is based on 30 years of hourly data, using Latin Hypercube Sampling and Iman-Conover transformation to incorporate correlation among uncertain parameters. A fast-forward heuristic algorithm is developed to solve the model efficiently. Applied to a case study on the EU, results show promise for this approach in designing multi-period supply chain networks that work well under each scenario

4 - Green Hydrogen Supply Chain Network Design for Aviation: Multi-Period Optimization Model with Seasonal Temporal Resolution

Akin Ögrük, Christian Thies

Hydrogen-based propulsion concepts for aircraft are considered a promising technology towards the decarbonization of aviation. While the development of respective aircraft models is in progress, questions regarding the supply network of green hydrogen are arising. We present a multi-period mixed-integer programming model for the hydrogen supply chain network design problem focusing on the aviation sector. The model minimizes the total network cost by making strategic decisions (e.g. suppliers, locations, capacities, transportation infrastructure) and tactical decisions (e.g. hydrogen flows, storage quantities) at different temporal resolutions. Our model formulation considers the spatially and temporally varying supply and demand of hydrogen, the techno-economic characteristics of hydrogen storage, liquefaction and transportation (e.g., economies of scale), as well as the specific requirements of hydrogen handling (e.g., losses). Model application is illustrated for German airports with local production and hydrogen import options, considering the projected development of the European Hydrogen Backbone pipeline infrastructure. Optimal network designs and results are presented and analyzed for different hydrogen supply and demand scenarios.

1 - Optimizing with attractor: combinatorial complexity of the traveling salesman problem

Weiqi Li

Although TSP has been placed in the subject of NP-completeness, it might not be as complex as expected. Often the seed of a solution is in the problem structure that creates the complexity. The intrinsic difficulty of TSP is due to the combinatorial explosion of tours in the solution space S , which increases in $(n-1)!$ as TSP size n increases. In TSP, a small set of $n(n-1)$ edges make up a large set of $(n-1)!$ tours in S . Let S' be a subset of S , if we can exponentially reduce S to S' using a polynomial-time local search algorithm, and S' can be polynomially searched by an exhaustive search algorithm, there is a polynomial algorithm for TSP. A local search can reduce S to S' quickly using the

edge matrix E of TSP as a reduction mechanism, because if one edge is removed in E , $(n-2)!$ tours are removed in S . Instead of searching for better tours in S , our effort is to remove bad edges in E . In a local search system, an attractor S' drives search trajectories into the vicinity of a globally optimal point in S . S' contains a small set of the most promising tours and is exponentially smaller than S , thus make an exhaustive search feasible. This new search paradigm is called optimizing with attractor. A new search algorithm consists of two search phases: local search phase quickly construct S' in S , and exhaustive search phase examines S' completely to find the optimal tour. TSP size can be reduced through its own data structure, thus it is a self-reducible problem.

2 - Exact and approximation algorithms for routing a convoy through a graph

Martijn van Ee, Tim Oosterwijk, René Sitters, Andreas Wiese

We study routing problems of a convoy in a graph, generalizing the shortest path problem (SPP), the travelling salesperson problem (TSP), and the Chinese postman problem (CPP) which are all well-studied in the classical (non-convoy) setting. We assume that each edge in the graph has a length and a speed at which it can be traversed and that our convoy has a given length. While the convoy moves through the graph, parts of it can be located on different edges. For safety requirements, at all time the whole convoy needs to travel at the same speed which is dictated by the slowest edge on which currently a part of the convoy is located. For Convoy-SPP, we give a strongly polynomial time exact algorithm using dynamic programming. For Convoy-TSP, we provide an $O(\log n)$ -approximation algorithm and an $O(1)$ -approximation algorithm for trees. Both results carry over to Convoy-CPP which - maybe surprisingly - we prove to be NP-hard in the convoy setting. This contrasts the non-convoy setting in which the problem is polynomial time solvable.

3 - A new approach for inter-sample avoidance using an integer polytope formulation

Johannes Schmidt, Armin Fügenschuh

To model the physics of the used vehicles in trajectory planning problems, Newton's equations of motion must be incorporated, discretized by numerical solution schemes. Thus, the position of the vehicle is in the model known only at a discrete set of points. Due to this lack of information, corner cutting can occur, i.e., the vehicle can abbreviate through an obstacle if it remains outside at every evaluation point again. Increasing the number of discrete time steps cannot resolve this problem completely and leads to higher computation times. To obtain always realistic solutions, corner cutting must be restricted, yielding so called inter-sample avoidance methods. We present a new approach to ensure inter-sample avoidance for polyhedral obstacles. The hyperplanes describing the obstacle divide the mission space into a set of subareas which can be encoded by binary vectors. These are used to ensure feasible movements without requiring more evaluation points or additional variables. We give a procedure to generate an integer polytope containing the feasible movements and derive an upper bound on the number of necessary constraints to describe it. The new approach is qualitatively tested against other inter-sample avoidance methods from the literature and its computational efficiency is studied in numerical experiments, using a mixed-integer linear program for trajectory planning of unmanned aerial vehicles and the state-of-the-art solver Gurobi.

4 - Modeling equipment scales of catering trolleys for flight operations

Hua-An Lu

Catering trolleys are one of the aircraft's standard load equipment for food-and-drink services in the cabin. Airlines must prepare sufficient scales to cope with all their passenger flight operations. The catering work must start a few hours before the flight departs, and loaded on-board trolleys cannot be directly reused after arrival before the cleaning process. Trolley types can be divided into regular and half carts by size and volume and are versatily used on every aircraft type. Aircraft galleys have specific areas with multiple blocks for the side-by-side storage of trolleys, with the principle of "all carts or no cart" for a block, even storing empty ones, to avoid trolleys arbitrarily moving while flying. This study exploited a time-space network graph to

express the movement of trolleys between airports and airports. An integer programming model based on this graph was proposed with the decision variables for the numbers of full and half trolleys on the arcs. The objective minimizes the total number of equipment scales subject to the flow conservation and constraints in handling catering trolleys with a safety stock level at each airport. This preliminary research reported the numerical experiments for a Taiwanese airline operating international flights. Tested cases consisted of 43 airports and 643 flights operated with four kinds of fleet and were solved within a reasonable time.

1 - A consensus fixing heuristic for the stochastic prize collecting TSP

David Pisinger

We consider the two-stage stochastic prize collecting traveling salesman problem, in which the objective is to maximize profit of served customers minus driving costs. The first-stage customers are to be served every day, while the second-stage customers fluctuate from day to day. The task is to select a subset of the first-stage customers, such that the expected earning is maximized. We present a highly parallel heuristics based on consensus fixing: The problems are solved independently for each scenario using a variable neighborhood search heuristic. Then, the scenarios try to reach consensus about fixing a single first-stage variable, using various score functions. The process of alternating between heuristic solution and variable fixing is repeated until all first-stage variables have been fixed. Computational results are reported for instances having up to 500 first-stage and 500 second-stage customers.

2 - Passenger and parcel share-a-ride problem with drones: Models and solutions

Rong Cheng, Yu Jiang, Otto Anker Nielsen, David Pisinger, Tom van Woensel

Growing concerns about traffic congestion and environmental pollution necessitate innovative solutions to enhance urban mobility for both people and goods. A novel approach involves combining passenger and parcel delivery services using demand-responsive buses (DRBs) and drones. This integration aims to reduce the number of vehicles on the road by combining the movement of passengers and parcels. In this scheme, each DRB is paired with a drone to work together. While DRBs accommodate both passengers and parcels, drones are used solely for delivering parcels. We introduce the concept of the induced Route Planning Problem for DRBs and drones, termed the Share-A-Ride Problem with Drones (SARP-D). We first developed an arc-based mixed integer programming model to formulate this problem, which can be solved by CPLEX for instances with up to 12 nodes. Then, we developed a path-based model and a column generation approach to solve medium instances with up to 50 nodes. The column generation approach achieves either optimal solutions or solutions very close to optimality within a 3-hour timeframe. Large instances with up to 200 nodes are solved by an adaptive large-neighborhood search metaheuristic, which can also efficiently solve vehicle routing problems with drones. Our experiments showed that SARP-D could reduce the number of used DRBs and DRB-traveled miles. We offer several key insights for management based on our research outcomes.

3 - Solving the Rainbow Steiner Tree Problem using Kernel Search

Lorenzo Tomasetti, Francesco Carrabs, Renata Mansini,
Lorenzo Moreschini

Given an undirected edge-colored graph with non-negative edge length, the aim is to find a minimum Steiner Tree that uses at most one edge for each color. The problem, called Rainbow Steiner Tree Problem (RSTP), is known to be NP-hard and can be used to model different real-world applications such as in wireless connectivity. Given the complexity of the underlying problem, we develop a simple variant of the Kernel Search algorithm based on the multicommodity flow formulation with rainbow constraints. Comprehensive work has been done on the Kernel search framework to enhance its effectiveness over the discussed problem. We test our approach on benchmark instances and compare its performance with both state-of-the-art algorithms and MIP solvers. Preliminary results are very promising.

4 - Extensions of Node-Depot Assignment Formulations for the Hamiltonian p -Median Problem

Francisco Canas, Luís Gouveia

Given a weighted complete undirected graph with weights on the edges and a positive integer p , the symmetric Hamiltonian p -Median Problem (HpMP) is to find a minimum weight set of p elementary cycles partitioning the vertices of the graph. We focus on a variant of the HpMP (the HpMP \geq) where solutions with strictly more than p cycles are also feasible.

We present new extensions of known node-depot assignment (NDA) compact formulations. NDA models are characterized by the inclusion of NDA variables, which are 1 if and only if node d acts as the depot of the cycle node i is in (or alternatively, if node i is "assigned" to node d), in addition to edge variables, which are 1 if and only if the corresponding edge is in some cycle. We extend these formulations with edge-depot assignment (EDA) variables, which are 1 if and only if node d acts as the depot of the cycle edge i,j is in. In this talk, we:

- 1 - Propose new formulations which use the EDA variables;
- 2 - Relate these models with formulations including only the edge and NDA variables;
- 3 - Present new inequalities in the space of the edge and NDA variables that are derived from the new models using EDA variables;
- 4 - Present computational results obtained with the new models.

Preliminary computational results show that the new models produce very strong LP relaxation bounds and, when used in combination with a modern ILP solver, allow for the resolution of instances with over one-hundred nodes.

from scheduled maintenance. However, deciding upon optimal schedules is a very complex task. Ideally, maintenance should be performed only when it is absolutely needed, minimising potential disruptions. In this paper we collaborate with Siemens to analyse a large data set consisting in log-data obtained from Computerised Tomography (CT) scan machines, with the objective of developing preventive maintenance based on anomaly detection. Here, the end-user (e.g., Hospitals) will have to make the decision of performing such maintenance based on the model predictions (and therefore, having to re-schedule patient's appointments). Having this into consideration we further develop explainable analytics that provide a visual representation containing warning time windows for future potential machine failures, and an explanation of why our model classifies them in that way.

2 - Research on profit control strategies of remanufacturing supply chain considering dual sales effort

Juhong Gao

Considering the consumption preference and fairness concern, this paper constructs a sub-channel remanufacturing supply chain in which manufacturer sell new products through retail channel and remanufactured products through direct channel. The optimal profit equilibrium strategy in the centralized and decentralized decision making of sub-channel remanufacturing supply chain with or without sales effort is studied by means of differential game analysis, considering the effect of time attenuation of advertising effect generated by dual sales effort of manufacturer and retailer. It is found that regardless of the initial advertising effect size of new products and remanufactured products, both manufacturer and retailer must take sales efforts in a certain period to stabilize the supply chain profits [U+FF0C] and there exists a critical value for the time to take sales efforts. In addition, it is revealed that the changing trend and the final stable value of the advertising effect of products depend on the optimal sales effort level and the effect of sales effort on the advertising effect, thus finding the changing law of the profit of the members of the supply chain and the total profit over time. This study provides a theoretical basis for supply chain member enterprises to effectively implement sales efforts on the profit control strategy of the sub-channel remanufacturing supply chain.

3 - Learning Decision-Focused Surrogate for Decision-Dependent Problems with Samples

Zhuojun Xie, Yiping Fang, Adam Abdin

Decision-Focused Surrogate (DFS) framework has been recently proposed to tailor parametrically tractable proxies for intricate optimization problems with nonlinear and/or nonconvex nature. In this work, we extend the frontier of DFS to a data-driven contextual stochastic decision-dependent setting where the endogenous uncertainty is affected by decision-dependent features. Moreover, the conditional distribution remains unknown, yet historical observations are available. Specifically, we substitute the unknown conditional distribution with a parametric linear model. To ensure the decision quality for specific tasks, we employ techniques from Decision-Focused Learning (DFL), including optimization differentiation and surrogate loss construction, to acquire gradient of decision quality concerning model's parameters. We examine the performance of DFS in a battery energy management problem within a renewable power system considering decision-dependent degradation. Our results demonstrate that compared to a surrogate model trained using standard regression loss, DFS can achieve better decision quality, especially when the model is misspecified. Despite the higher computational expense of learning DFS, our empirical analysis reveals that the trained surrogate can generate high-quality solutions for instances under similar conditions.

4 - Towards analyzing DNNs by robust adversarial examples created with MILPs

Rónán Rian Carl Richter, Jörg Rambau

The interest in the use of Deep Neural Networks (DNNs) has grown rapidly over the last few years. As an increasing number of people and businesses are using DNN-based systems and governments start to take actions to regulate the use of artificial intelligence, there is a growing demand for methods to analyze the trustworthiness of a DNN and the limits of its application. One classical illustration for showing weaknesses of DNNs, especially in the context of image recognition, are Adversarial Examples. These are slightly modified versions

1 - Preventive maintenance for computerised tomography (CT) scan machines: an anomaly detection approach based on log-data.

Felipe Maldonado

Preventive maintenance is a very critical topic for many industries. Particularly in healthcare, often the associated costs (monetary and social) of unplanned downtimes are much higher than those coming

of input data, that lead a DNN into wrong classifications. As Fischetti and Jo (2018) have shown, Adversarial Examples can be generated by using mathematical programming methods. Thus, these Adversarial Examples are provably optimal in respect to a given criterion, e.g. the distance to some given input data. However, the structure of these examples highly depends on the parameters of the network. To address this point, we will present a mixed-integer programming model for generating Adversarial Examples, that are robust with respect to small changes in the weights and biases of a DNN. For relaxations of the model, we will illustrate the impact of robustification on Adversarial Examples. Furthermore, we present experimental results on the influence of training data on the distance of Adversarial Examples and on the transferability of our examples.

1 - Dynamic Berth Allocation Policies at Deep-sea Terminals

Orkun Tunay, Pieter van den Berg, Rob Zuidwijk, Debjit Roy

While deep-sea vessels play an important role for the revenue streams of container terminals, barges and feeders play an important role in ensuring the functioning of the transshipment and hinterland transportation operations. Besides, the roles of feeders and barges are further leveraged as a cost and emission-efficient alternative to long-haul trucking. These different classes of vessels compete for the same berth space in container terminals. The terminal operators conventionally have the tendency to fully prioritize deep-sea vessels. However, with the increasing incentives and regulatory pressure for the increase of barge and feeder throughput, some terminal operators started to allocate dedicated berths for barges and feeders. In this paper we will study the berth allocation problem in order to find a pareto-optimality frontier that balances barge throughput and deep-sea vessel waiting times. Barges and feeders which are of smaller volume, occupy a smaller space and have a shorter expected handling time. By using analytical methods from Queuing Theory, we will first demonstrate the pareto-efficiency of different heuristics of berth allocation policies, i.e. dedicated terminal spaces, barge limits, motivated by the current industry practices. Based on the insights that we receive from analytically tractable systems, we will design a Markov Decision Process to propose a better pareto-optimality frontier with dynamic policies.

2 - Data-driven integer programming models for installation of offshore wind turbines.

Charles Emeka Onyi, Mahdi Doostmohammadi, Kerem Akartunali

Millions of pounds are involved in the construction of offshore wind turbines. Therefore, there is a need to optimize the whole process to reduce the cost and duration of the final procedure involved in wind energy generation. Specifically, this project focuses on modeling the procedure for the installation of offshore wind turbines as a mixed integer linear programming and the use of exact methods to solve those models. The objective is to minimize the total cost used in the installation procedure. To obtain an optimal solution, we devise a shortest path-like formulation using strong multicommodity flow models of the network. We show that this new formulation is NP-Hard. We propose a polyhedral analysis of the set of solutions by identifying novel problem-specific valid inequalities required to characterize the convex hull of feasible solutions. Also, we design an efficient cutting plane

algorithm that identifies the optimal configuration of vessel schedules that minimizes the installation duration and cost. We present preliminary computational results on the problem specific and the literature instances that are related to the problem formulation. Also, computational instances will be tested by real-world data collected from offshore wind farm installations.

3 - Strategic capacity planning for logistics service providers

Ioannis Fragkos

Logistics service providers (LSPs) employ transportation assets like car wagons and containers to meet customer needs. To adequately service these needs, it is essential to use assets with the right capacity for each transportation task. The time needed for these operations can vary due to disruptions in the network, which introduce the need to have additional resources. This situation leads to a complex version of the newsvendor problem, where the LSP must decide the number of assets to acquire and plan their deployment to cater to demands that specify a certain capacity but have an uncertain duration. Any demand that exceeds the planned capacity can be met by using spot assets, although at a higher expense. This concept is applied to an LSP that leases train wagons yearly and manages demand fluctuations through occasional spot train rentals. We formulate a two-stage stochastic program to represent this problem. The formulation's structural features, combined with column generation, lead to an efficient solution method. The effectiveness of our method is demonstrated through computational studies.

4 - A rich model for the tramp ship routing and scheduling problem — solved through column generation

Alberto Tamburini, David Pisinger, Nina Lange

We consider the Tramp Ship Routing and Scheduling Problem (TSRSP) in which we plan routes for a homogeneous fleet of tramp shipping vessels operating on a combined contract and spot market. Earlier research has been fragmented due to variations in the side constraints studied, hence we present the first unified model that can handle speed optimization, chartering costs, bunker planning, and hull cleaning. The model is solved by column generation, where the columns represent the possible routing of a vessel while the master problem keeps track of the binding constraints. The pricing problem is solved efficiently using a time-space graph, making it possible to solve relatively large instances of the TSRSP in a very short time. Detailed computational results are reported giving insight into both the algorithmic performance but also answering operational and tactical questions for the tramp shipping company and the tramp shipping sector.

Invited session

Chair: Benjamin Müller

1 - What's New in FICO Xpress Solver?

Timo Berthold

We will give an overview of the latest enhancements, the newest features, and the most recent performance improvements in the FICO Xpress Solver for mixed-integer linear and nonlinear optimization problems. These include new heuristics, cutting and branching techniques, an augmented API, and updates to our global MINLP solver.

2 - Whats new in Gurobi 11

Michael Winkler

We will give an overview about recent developments and performance improvements within Gurobi 11.

3 - Recent Advances in the SCIP Optimization Solver

Suresh Bolusani

SCIP is an open-source optimization solver for mixed-integer linear and nonlinear optimization problems and a framework for constraint integer programming and branch-cut-and-price implementations. This talk will highlight the latest developments in SCIP 9.0, released in February 2024, including symmetry handling, constraint handlers, primal heuristics, cut generation and selection techniques, branching rules, and LP interfaces. SCIP 9.0 has an improved overall performance in solving time, the number of nodes in the branch-and-bound tree, and the solver's reliability.

4 - Recent advances in the Cardinal Optimizer

Benjamin Müller

In this talk, we present the recent developments in the Cardinal Optimizer (COPT). We discuss some key techniques that contributed to the performance improvements of our MIP solver and present performance numbers of the latest COPT release for all problem classes.

1 - Estimation of Online Advertising Effectiveness using a Coarsened Exact Matching Framework

Vamanie Perumal, Palaniappan Ramu

Geo experiments are a method of choice to estimate online advertising effectiveness. It is challenging to relate ad spend (treatment) in each geo and the ensuing time series responses, such as sales. The return on ad spends (ROAS) is the difference between responses obtained during treatment (after-data) and the counterfactual responses if treatment had not occurred (before-data). Since we obtain only after-data for treated geos, evaluating the ROAS depends on how well the before-data are modelled. A typical approach for modelling before-data includes estimating the behavior of treated geos using the behavior of control geos. An inevitable problem is to find control geos homogeneous to treated geos so that any difference can be directly attributed to the treatment. To tackle the challenges mentioned above, we propose a time series based statistical matching framework. The selected time series features used as covariates vary naturally among all geos without being influenced by the treatment. We achieve a balanced covariate distribution between control and treated geos using Coarsened Exact Matching (CEM). The weights obtained from CEM are used to build a time-varying negative binomial regression model for counterfactual estimation of before-data for treated geos. We demonstrate results using real-time online advertising data. We observe significant improvement in homogeneity between control and treated geos, thereby improving the accuracy of incremental impact measurement.

2 - Algorithmic pricing and collusion on a price comparison website

Charlie Lindgren, Kenneth Carling, Ross May, Niklas Rudholm

Empirical evidence identifies a large proportion of retailers using algorithmic pricing for making price decisions. This opens several questions surrounding tacit collusion and its detrimental effects on competition and consequently consumers in the form of supracompetitive prices. As an initial step towards answering whether or not tacit collusion is happening among pricing algorithms, one need to first identify which retailers are using such technology. We have defined two new statistical markers for identifying pricing algorithms in low-resolution

data. One of the markers adapts counting the number of price changes by instead computing the average rate of price change per retailer over all its products both within and across countries. The other, novel, marker computes the persistence of a retailer in the marketplace. Using robust standardization of the two markers and applying a heuristic based on appropriate thresholds of these standardized markers, we have identified varying numbers of retailers within and between countries for the product categories employing algorithmic pricing. We have therefore created a new heuristic for identifying pricing algorithms in low-resolution data sets. Furthermore, this heuristic allows for further research in empirically identifying whether or not tacit collusion exists among algorithms and the effects such pricing has on the profitability of the retailers who employ such technology compared to those who do not.

3 - A location and assortment problem for e-commerce distribution with returns and transshipments

Joris van Oers, Quang-Vinh Dang, Zumbul Atan, Ivo Adan

As customer demand changes over time, reevaluation of strategic decisions concerning network design becomes imperative. However, this entails significant investment in capital goods, necessitating resilience to future disruptions. Consequently, this crucial decision often gets deferred in practice, leading to inefficient distribution networks. To address this challenge, we introduce a robust decision-support tool for evaluating strategic choices under varying scenarios. Specifically, our focus lies on the optimization problem of facility location and network design (FLNDP) within a distribution network. This involves selecting the optimal subset of new warehouses to open from a set of potential locations, taking into account the significant return flow of items. In addition, a strategic planner can opt to equip the opened warehouses with facilities for inspecting returned items at fixed costs. Our contribution is twofold. First, we develop a mathematical model to solve the FLNDP that allows for transshipments between warehouses, in contrast to earlier literature. This results in notable differences in the optimal solution of the network design, due to the imposition of fixed setup costs for transportation. Second, we provide managerial insights by evaluating a use case with real-world data, featuring disruptions from a pandemic and geopolitical shifts within Europe.

4 - Towards effective and efficient personalized ranking in news article recommender systems: balancing clicks and diversity

Lukas De Kerpel, Dries Benoit

As the consumption of news articles continues to shift towards online platforms, personalized news recommendation engines have become an indispensable asset for news providers seeking to enhance users' reading experience.

However, as the shelf life of news items is limited, traditional collaborative filtering approaches fall short to provide accurate recommendations because they heavily rely on user signals, which may not be readily available for newly introduced news articles. Contextual multi-armed bandits (CMAB) emerge as a promising alternative by leveraging intrinsic characteristics and attributes of both news items and users.

While CMAB systems predominantly optimize for clicks, this research argues for a more comprehensive evaluation framework that also promotes the diversity of recommended items, as diversity-aware recommenders are able to respond to news readers' needs on information variety and to expose users to counter-attitudinal behavior.

By conducting a benchmark study on a large-scale proprietary dataset obtained from an international news provider, we demonstrate the feasibility of creating an effective and efficient personalized news article recommendation system based on CMAB models while simultaneously addressing the multifaceted nature of news article recommendation quality. In particular, this study highlights the necessity of considering diversity alongside clicks to enhance user satisfaction and engagement.

1 - Feature selection in linear SVMs: a scalable SDP decomposition approach using a hard cardinality constraint

Bo Peng, Immanuel Bomze, Laura Palagi

In this talk, we focus on the feature selection problem in linear SVMs by using a hard cardinality constraint. The problem is first reformulated into mixed-integer form, for which a novel SDP relaxation is proposed. Exploiting the sparse pattern of the relaxation, we decompose it and obtain an equivalent SDP relaxation in a three-dimensional positive semi-definite cone. Based on the decomposed SDP relaxation, we propose heuristics using the information of its optimal solution. Moreover, an exact procedure is proposed by solving a sequence of mixed-integer decomposed SDPs. Numerical results on classical on-line datasets are reported.

2 - A branch-and-cut algorithm for biclustering via semidefinite programming

Antonio M. Sudoso

Biclustering, also called co-clustering, block clustering, or two-way clustering, involves the simultaneous clustering of both the rows and columns of a data matrix into distinct groups, such that the rows and columns within a group display similar patterns. Focusing on the densest k -disjoint-biclique problem as a biclustering model, the objective is to identify a set of k disjoint bicliques within a weighted complete bipartite graph such that the sum of the densities of the complete subgraphs induced by these bicliques is maximized. A branch-and-cut method is proposed to achieve global optimality. The upper bound routine involves solving a semidefinite programming relaxation, employing a cutting-plane approach to strengthen the bound. For the lower bound, a maximum weight matching rounding procedure is designed, leveraging the solution of the relaxation solved at each node. Computational results on both synthetic and real-world instances show that the proposed algorithm is capable of solving instances with a size ten times larger than general-purpose solvers.

3 - Combining interior and exterior penalty for nonlinear constrained black-box optimization problems

Andrea Brillì, Everton Silva, Ana Luisa Custodio, Giampaolo Liuzzi

This research explores an approach to addressing mathematical optimization problems characterized by nonlinear objective functions and constraints, particularly in situations where derivatives are unavailable. A Sequential Penalty Approach is introduced, incorporating a Logarithmic Barrier for managing inequality constraints and an Exterior Penalty for equality constraints. Our proposed method aims to providing a comprehensive solution for a wide range of nonlinear optimization challenges. This strategy, proposed for the first time in a derivative-free setting in the framework of linesearch methods, is adapted and incorporated into SID-PSM algorithm, a generalized pattern search method, allowing to effectively handle general nonlinear constraints. Under reasonable assumptions regarding the smoothness of the functions, convergence is established, without any convexity assumption. Empirical validation is conducted through experimentation on a diverse set of optimization problems. The results corroborate not only the efficacy of the proposed approach but also its practical utility. The direct search algorithm, when complemented by the Logarithmic Barrier and Exterior Penalty, consistently exhibits promising numerical results, demonstrating the potential of the technique.

4 - Estimation of Hydraulic Parameters Using the Augmented Lagrange Method

Fabio Fortunato Filho, José Mario Martínez

The importance of hydraulic studies is undeniable in understanding the behavior of fluids in natural and constructed environments, such as channels, rivers, and streams. The Saint-Venant equations, a widely adopted one-dimensional model, are crucial for this understanding. However, ensuring the representativeness of these equations requires considering all boundary conditions, which includes estimating the Manning roughness coefficient. This estimation, essential for accounting for fluid friction with different surfaces, is a notable challenge due to the coefficient's variability along the channel. In this context, we propose an approach that utilizes the Augmented Lagrange Method to minimize errors in solving differential equations at different points. Additionally, we employ the PRIMA software (BOBYQA) with space reduction based on interpolation to estimate the Manning coefficient. This methodology was applied to the East Fork river, and even with few days of training data, we achieved relevant results in describing the behavior of this river.

1 - Joint production and human replacement optimization policy for a deteriorating manufacturing system

Jean-Pierre Kenne

This paper tackles the integration of production and human resource management planning, which considers the operator as a production unit subject to degradation according to age, in the context of an unreliable production system in a considerable state of deterioration. The deterioration of the production unit process has a twofold effect on its reliability and continuity, and therefore, to moderate the effects of this deterioration, a replacement action can be conducted based on the state of the system. The objective of the study is to determine an appropriate production policy and replacement strategy in order to meet customer demand. A combination of stochastic dynamic programming and numerical methods are used to solve this optimal control problem. In addition, a numerical example is provided to illustrate the usefulness of the proposed approach, as well as to study the interaction between a given production strategy and human resource management. The effect of the new approach based on a logical implementation is presented following a sensitivity analysis of the numerical example. Regarding the results, a comparative study between recent research and the proposed policy is presented. Finally, an implementation chart is drawn up to guide decision-makers in setting production rates and managing human resources to meet customer demand.

2 - Non-committed cost auditing in supply chain contracts

Zhengping Wu, Jing Li, Wanshan Zhu

As a widely used tool in supply chain practice, audits can alleviate the supply chain inefficiencies under asymmetric information. In this study, we investigate the impact of the commitment to a cost audit on the optimal supply chain contract design, and the corresponding audit efficiency.

3 - Optimal control of one economic differential model of market relations

Phridon Dvalishvili, Aleksandre Mosidze, Tamaz Tadumadze

For market relations, a controlled differential model with supply-demand functions and with delay parameter in control is constructed. We call the difference between supply and demand functions the disbalance index. It is assumed that consumer demand at any point in time will be satisfied through pre-ordering. To describe the development of the market equilibrium process over time, a dynamic model with an integral disbalance index is considered. For the proposed model an optimal control problem is studied. Namely, the existence theorem of an optimal control and the necessary conditions for optimality are formulated on the basis of results obtained in [1, 2]. In the case of a linear function of supply and demand, all controls that are doubtful of optimality are detected. An example is discussed at the end. Another case of optimal control of market relations was studied in [3].

4 - Dynamic Programming-based formulations and algorithms applied to inventory management: A systematic review

Edson Souza, Stefan Creemers, Tanja Mlinar, Maud Van den Broeke

Dynamic programming (DP) has been consistently employed in inventory management, especially in multi-period formulations, contributing to our understanding of the field. Despite the challenges posed by the curse of dimensionality, DP-based formulations have evolved over time to alleviate its effects, especially as inventory problems become more complex. This review aims to analyze the use and evolution of DP-based methods in inventory management, encompassing 287 articles. To provide a comprehensive overview of DP-based formulations for inventory problems, we propose a typology classification, centered inventory- and DP-based criteria, by categorizing inventory problems based on the types of decisions explored and the main characteristics of the problem investigated, and by identifying DP approaches employed. We emphasize the practical implications of DP approaches in industry, specify limitations in existing studies, and suggest future research directions. In particular, we stress the relevance of considering uncertainties beyond demand-related factors, integrating sustainability aspects into DP approaches such as incorporation of government subsidy levels and regulations, and exploring inventory problems in reverse logistics and remanufacturing. Furthermore, we highlight the need for further development of applied studies utilizing Approximate and Hybrid DP in combination with data-driven methodologies to address challenges in real-life inventory scenarios.

1 - Alternating Projections Methods for Matrix Completion: Regularized and Inexact Projections

Mattia Silei, Stefania Bellavia, Simone Rebegoldi

Matrix Completion (MC) involves reconstructing the missing entries of a partially observed matrix M by leveraging the assumption that M has low rank [1]. Problems that can be approached with MC arise in various fields, such as recommendation systems, image inpainting, and compressed sensing. Our work starts from the idea of reformulating MC as the problem of finding a matrix in the intersection of two sets: the set of matrices with the same observed entries as M , and the nonconvex set of matrices of rank less than or equal to r . This is a feasibility problem (FP), which generally involves finding a point x in the intersection of two sets A and B . Since the 1950s [2], the Alternating Projection Method (APM) has been proposed to solve FP. Starting from a point in B , APM generates a sequence of points by alternately projecting onto A and B . We will discuss two theoretically well founded regularized variants of the method, employing exact projections (RAPM) and inexact projection onto the set B (iRAPM). The obtained theoretical results guided us to the definition of a new stopping criterion for the Krylov iterative method employed for computing the approximate truncated SVD (needed to compute the inexact projection onto the rank set). Some numerical experiments to validate the convergence results and the performance of the studied methods will be also shown.

2 - Fractional graph Laplacian for image reconstruction

Marco Donatelli, Stefano Aleotti, Alessandro Buccini

A popular approach for regularization involves replacing the original problem with an optimization problem that minimizes the sum of two terms: an l_2 term and an l_q term with q smaller than or equal to one. The first penalizes the distance between the measured and reconstructed data, while the second imposes sparsity on certain coefficients of the computed solution.

In [1], we propose to use the fractional Laplacian of a properly constructed graph in the l_q term to compute extremely accurate reconstructions of the desired images. Furthermore, we propose automatic approaches to determine the involved parameters so that the proposed method is completely plug-and-play. We show that the algorithm, under some reasonable assumptions, is a regularization method. Some selected numerical examples show the performances of our proposal.

3 - A multiplicative components framework for joint correction and segmentation of magnetic resonance images

Marco Viola, Laura Antonelli, Valentina De Simone

The segmentation of Magnetic Resonance Images (MRIs) is a challenging task due to the artifacts introduced by the acquisition process, namely intensity inhomogeneity (also known as bias field) and noise (which follows a Rician distribution). In this work we introduce a model called MICCT, based on the Multiplicative Intrinsic Components framework and Cartoon-Texture decomposition techniques, to perform simultaneous denoising and bias-field correction of an MRI. The output of MICCT can be then segmented with any state-of-the-art segmentation strategy. We introduce an ADMM strategy to solve the nonlinear and nonconvex model associated with MICCT and analyse its theoretical convergence properties. Finally, we present some numerical experiments showing the effectiveness and the competitiveness of the proposed approach (combined with a K-means strategy) in the segmentation of noisy MRI from the BrainWeb database.

4 - Convergence analysis of optimization-by-continuation proximal gradient algorithm and some primal-dual extensions

Ignace Loris

In this work we focus on the concept of optimization-by-continuation as a strategy for solving a set of optimization problems in about the time it would take to solve a single instance of them. Each cost function is a different linear combination of two convex terms, one differentiable and the other prox-simple. Such optimization problems occur frequently in the numerical solution of inverse problems (data misfit term plus penalty or constraint term), and the relative weight of both terms is often not known in advance. The algorithm's special feature lies in its ability to approximate, in a single iteration run, the minimizers of the cost function for many different values of the parameters determining the relative weight of the two terms. We also discuss the same problem in the presence of a third term in the cost function which is the combination of a prox-simple function and a linear map. As a special case, one recovers a generalization of the primal-dual algorithm of Chambolle and Pock.

1 - The Robust Bike Sharing Rebalancing Problem: Formulations and a Branch-and-Cut Algorithm

Bruno Bruck, Walton Pereira Coutinho, Pedro Munari

Bike sharing systems (BSSs) are an important component of sustainable urban transportation, providing flexible and eco-friendly alternatives for city logistics. However, these systems often face challenges with unbalanced bike distribution among stations, requiring rebalancing operations to ensure efficient operations. Adding to this complexity is the uncertain demand at stations, which can further complicate rebalancing efforts even during off-peak hours. This work introduces the Robust Bike Sharing Rebalancing Problem (RBRP), which employs robust optimization to improve rebalancing operations in BSSs. Despite the significant impact of uncertainty on system performance, few studies have addressed this aspect in the literature. We propose two new formulations and a tailored branch-and-cut algorithm for the RBRP. The first formulation is compact, leveraging the linearization of recursive equations, while the second relies on robust rounded capacity inequalities and feasibility cuts. Computational results based on benchmark instances demonstrate the effectiveness of our approaches, highlighting the benefits of robust solutions in supporting decision-making for BSSs.

2 - A rolling horizon heuristic approach for a multi-stage stochastic waste collection problem

Andrea Spinelli, Francesca Maggioni, Tania Ramos, Ana Barbosa-Povoa, Daniele Vigo

We present a multi-stage stochastic optimization model for a waste collection routing problem. The problem is modeled as an inventory routing problem where decisions are related to the selection of bins to be visited and the corresponding visiting sequence in a predefined time horizon. The aim is the maximization of the total expected waste collection at lowest transportation cost, considering uncertainty in the waste accumulation rate in the network bins. Stochasticity in waste

accumulation is modeled through scenario trees generated via conditional density estimation and dynamic stochastic approximation techniques. The model is solved through a rolling horizon approach, providing a worst-case analysis on its performance. Computational experiments are carried out on instances based on real data of a large Portuguese waste collection company. The impact of stochasticity on waste generation is examined through stochastic measures, and the performance of the rolling horizon approach is evaluated. Some managerial insights are finally discussed.

3 - Models and solution approaches for the consistent vehicle routing problem under stochastic travel and service times

Yossiri Adulyasak, Seyede Saeede Hosseini, Louis-Martin Rousseau

We explore a consistent vehicle routing problem for home health care under uncertain travel and service times. In this problem, the planner must schedule and route a group of care workers to visit patients multiple times over a planning horizon while ensuring service consistency so that each patient will be serviced by the same care worker at the same time slot every time the service is provided. This problem variant extends the home health care routing and scheduling problem (HHCSP) to include service level constraints under stochastic travel and service times. We propose a stochastic solution framework where the uncertainty is represented by (i) a discrete scenario set and (ii) an extreme value theory-based (EVT-based) approximation. A unified branch-and-check algorithm that leverages constraint programming (CP) to handle the subproblem is developed to efficiently solve the stochastic models with these uncertainty representations. Results show that the stochastic optimization framework can efficiently handle practical benchmark instances and produce schedules with significantly improved service levels than the deterministic model.

4 - The Waste Collection Vehicle Routing Problem with Stochastic Time Dependent Demand Increments

Giuseppe Stecca, Simona Mancini, Francesca Vocaturo

We focus on a vehicle routing problem with stochastic time-dependent demand increments. In this problem, a homogeneous fleet of vehicles must visit a set of collection points with the aim of removing waste. We divide the planning horizon (day) in not-overlapping time slots. Each collection point must be visited exactly once during the planning horizon and it has a known initial demand which may increase along the day. In fact, for each collection point and for each time slot, additional demand may arise. The (uncertain) demand increments are revealed upon arrival at the collection points. The goal is to minimize the expected total cost which also considers a penalty for the residual quantity of waste accumulated at the collection points after they have been visited. We present a two-stage stochastic program and discuss specific recourse policies for the problem under study.

Game Theory, Solutions and Structures I

Stream: Game Theory, Solutions and Structures

Invited session

Chair: *Encarnación Algaba*

Chair: *Tamás Solymosi*

1 - TU-games with utility: characterization sets for the u-prenucleolus

Zsófia Dornai, Miklós Pintér

The u-prenucleolus is a generalization of the pre-nucleolus using utility functions. The u-prenucleolus can also be considered as a generalization of the per-capita pre-nucleolus. We prove the generalizations of some important theorems about the pre-nucleolus to the u-prenucleolus, such as Kohlberg's theorem and the theorem of Katsev and Yanovskaya

about a sufficient and necessary condition on the unicity of the u-prenucleolus. We also prove a generalization of Huberman's theorem by defining the u-essential coalitions and showing that these coalitions characterize the u-prenucleolus of u-balanced games. Considering the dual of the game, we define the u-anti-prenucleolus, and show that the u-anti-essential coalitions characterize it. Using these results, we get that in the primal game the u-dually-essential coalitions - which generalize the dually essential coalitions defined by Solymosi and Sziklai - characterize the u-prenucleolus. This way, we get a characterization set for the u-prenucleolus that differs from the set of u-essential coalitions.

2 - Random partitions, potential of the Shapley value, and games with externalities

André Casajus, Yukihiko Funaki, Frank Huettner

The Shapley value equals a player's contribution to the potential of a game. The potential is a most natural one-number summary of a game, which can be computed as the expected accumulated worth of a random partition of the players. This computation integrates the coalition formation of all players and readily extends to games with externalities. We investigate those potential functions for games with externalities that can be computed this way. It turns out that the potential that corresponds to the MPW solution introduced by Macho-Stadler et al. (2007, J. Econ. Theory 135, 339-356) is unique in the following sense. It is obtained as the expected accumulated worth of a random partition, it generalizes the potential for games without externalities, and it induces a solution that satisfies the null player property even in the presence of externalities.

3 - Coalitional Manipulations and Immunity of the Shapley Value

Frank Huettner, Christian Basteck

We consider manipulations in the context of coalitional games, where a coalition aims to increase the total payoff of its members. An allocation rule is immune to coalitional manipulation if no coalition can benefit from internal reallocation of worth on the level of its subcoalitions (reallocation-proofness), and if no coalition benefits from a lower worth while all else remains the same (weak coalitional monotonicity). Replacing additivity in Shapley's original characterization by these requirements yields a new foundation of the Shapley value, i.e., it is the unique efficient and symmetric allocation rule that awards nothing to a null player and is immune to coalitional manipulations. We further find that for efficient allocation rules, reallocation-proofness is equivalent to constrained marginality, a weaker variant of Young's marginality axiom. Our second characterization improves upon Young's characterization by weakening the independence requirement intrinsic to marginality.

4 - On the Owen core of many-to-one assignment games

Tamás Solymosi, Regina Radanovits

Many-to-one assignment games (Sotomayor, 1992) are extensions of one-to-one assignment games (Shapley and Shubik, 1972). It is known that the core of many-to-one assignment games is non-empty and has the two side-optimal special vertices. We consider many-to-one assignment games as special linear production games (Owen, 1975) and investigate the Owen core (the set of core allocations obtained from the dual optimal solutions of the LP for the grand coalition). Unlike in assignment games where the two sets coincide, in many-to-one assignment games the dimension of the Owen core is at most the number of players allowed to be assigned to several players of the other type, while the dimension of the core is at most the number of the 1-capacity players. We show that the Owen core of a many-to-one assignment game can be described as the core of an associated assignment game. This facilitates the application of various results known for the core of assignment games to the Owen core of many-to-one assignment games. For example, based on the graph-theoretic characterization of the two side-optimal core vertices (Solymosi, 2023), we show that the same allocation maximizes the payoffs for all 1-capacity players both in the Owen core and in the core, but the allocation which minimizes all these payoffs in the Owen core need not be an extreme point of the core. We also provide conditions for the coincidence of these minimizing allocations.

Vector and Set Optimization I

Stream: Vector and Set Optimization

Invited session

Chair: Miguel Sama

1 - Cone-compactness and applications in set optimization

Marius Durea, Elena-Andreea Florea

We study the concept of cone-compactness for a subset of a normed vector space from the perspective of a sequential characterization under a separability assumption. Then we show that this concept is naturally involved in the investigation of several issues related to set optimization such as stability problems, conic cancellation laws, subdifferential calculus and optimality conditions.

2 - Vector optimization with variable ordering structure: a unifying approach

Radu Strugariu

We investigate the possibility to unify the different approaches considered in the framework of vector optimization with variable ordering structures. As consequence, we analyze the incompatibility principle between optimality and openness and deduce new optimality conditions in this context.

3 - The Interval-valued optimization problem through variational inequality problems on Hadamard manifolds

Gabriel Ruiz-Garzón, Rafaela Osuna-Gómez, Antonio Rufán-Lizana, Antonio Beato-Moreno

The aim of this work is to find the solutions of the Interval-valued Optimization Problem through the Variational Interval-valued Problem on Hadamard manifolds. We will use the gH-differentiability for interval-valued functions on Hadamard manifolds and we will extend the Stampacchia and Minty versions of these variational problems given by Euclidean spaces and real valued functions to interval-valued functions on Hadamard manifolds.

4 - Stability analysis of state constrained multiobjective elliptic control problems

Miguel Sama, Akhtar Khan

This presentation focuses on a multiobjective elliptic control problem with state constraints. Specifically, we show how we can apply recent results on stability estimates for these kinds of problems (Khan, Sama, Optimization 72(4), 1009-1036, 2023) to obtain numerical error estimates for different discretization schemes.

Hybrid Classical-Quantum Algorithms

Stream: Quantum Computing Optimization

Invited session

Chair: Caroline Prodhon

Chair: Wesley Coelho

1 - Quantum pricing-based column-generation framework for hard combinatorial problems

Wesley Coelho

In this work we present a complete hybrid classical-quantum algorithm involving a quantum sampler based on neutral-atom platforms. This approach is inspired by classical column-generation frameworks developed in the field of operations research and shows how quantum procedures can assist classical solvers in addressing hard combinatorial problems. We benchmark our method on the minimum vertex coloring problem and show that the proposed hybrid quantum-classical column-generation algorithm can yield good solutions in relatively few iterations. We compare our results with state-of-the-art classical and quantum approaches.

2 - Mixed Integer Linear Programming Solver Using Benders Decomposition Assisted by Neutral Atom Quantum Processor

Anna Joliot, Wesley Coelho, M. Yassine Naghmouchi

This work presents a new hybrid classical-quantum approach to solve Mixed Integer Linear Programming (MILP) using neutral atom quantum computations. We apply Benders Decomposition (BD) to segment MILPs into a master problem (MP) and a subproblem, where the MP is addressed using a neutral-atom device, after being transformed into a Quadratic Unconstrained Binary Optimization (QUBO) model. To solve the QUBO, we develop a heuristic for atom register embedding and apply Quantum Approximate Optimization Algorithm for pulse shaping. In addition, we implement a Proof of Concept that outperforms existing solutions. We also conduct preliminary numerical results, outperforming classical BD approaches where the MP is solved using simulated annealing. To the best of our knowledge, this work is the first to utilize a neutral atom quantum processor in developing an automated, problem-agnostic framework for solving MILPs through BD. Looking to the future, our objective is to scale and diversify our instances. This presents difficulties related to the limits on the number of qubits and the convergence of the algorithm. To overcome resource limitations, one can set a maximum number of qubits and implement an iterative process that guarantees the quality of the solution. When facing issues with convergence, we can consider multi-cuts, which involves generating multiple solutions for the MP and selecting a specific subset of Benders cuts to not surcharge the MP.

3 - Application of quantum computing in securities transactions settlement framework

Ekaterina Alekseeva, Nicolas Wolters

A securities transaction is an exchange of securities versus payment in currency between two financial actors. The transaction is settled, if, *inter alia*, there are sufficient amounts of resources on the corresponding cash and securities accounts. Each night more than four hundred thousand transactions over a billion euro are settled in batches. Banque de France is in charge of Mathematical Optimization Module (MOM), which is a component of a large European transactions settlement platform named T2S. Given a batch and the limited time, MOM looks for a subset of transactions to settle whose size is as large as possible respecting all business constraints and taking advantage of some financial features reducing the number of failed transactions. It is composed of preparatory, construction and improvement solution phases. Since the batch size is too large, no algorithm can find neither optimal nor approximate solution for the entire batch on a conventional computer. Thus, MOM's preparatory phase splits a batch of transactions into the subsets to address smaller problems. The current splitting procedure has long runtime and its quality affects the final number of settled transactions. In this work, we present an approach that would improve the splitting results and the MOM's outcome. It is based on a Quadratic Unconstrained Binary Optimization solved by a Quantum Approximate Optimization Algorithm and implemented on the available quantum devices via Qiskit platform.

4 - Solving an MBDA's use case related to optimal assignment on current IBM Quantum Computers

Edouard Debry, Davide Boschetto, Rachel Roux, Janis Aiad, Alexandre Kotenkoff

In this communication, we aim to present the solving of an MBDA's use case related to optimal assignment, onto IBM online QPUs. The Quantum Approximate Optimization Algorithm (QAOA) (Farhi et al. 2014) is the base of our Variational Quantum Algorithm developed.

We compare two methods to account for constraints, first primarily by integrating them into the Cost Hamiltonian with Lagrangian multipliers and second, by adapting the Mixer Hamiltonian according to (Wang et al. 2022) and (Fuchs et al. 2022). For the former, determining the optimal Lagrangian multipliers is generally a challenging task and the integration of constraints into the Cost Hamiltonian can significantly increase the associated circuit depth. The latter method aims to reduce the overall Hilbert space to only feasible solutions, which lets get rid of Lagrangian multipliers but may significantly enlarge the circuit associated to the Mixer Hamiltonian and make the initial state harder. It is then interesting to compare the circuit depth of both methods with respect to how well they are able to statistically put forward optimal solutions against non-optimal and non-feasible ones, still for relatively small sized instances, to fit on current QPUs.

Simulation of organizations I

Stream: Agent-based Models in Management, Economic and Organisation Sciences

Invited session

Chair: Friederike Wall

1 - A Computational Account of Complex Systems

Davide Secchi, Martin Neumann

This study is concerned with understanding and classifying the variety and difference among complex systems. Definitional differences usually stem from the disciplines where complexity was first detected and analyzed. They are also characterized by emphasis on one specific element of the system, being its composing entities, their interrelations, entropy, or emergence, to name a few of the most popular. These classifications generate a broad definitional space for complexity, leading to large differences among types of complexity. In other words, not all complexity is made equal. The issue of concern for this paper is to formally qualify these differences by using a series of agent-based computational simulation models where complexity is manipulated by modifying one component at the time. This should be able to provide a map of complexity, from more to less intuitive, from more to increasingly less predictable, and from single- to multi-layered. The research is structured around a model grounded in the social sciences, more specifically it illustrates intra-organizational dynamics as an exemplar of complexity in social systems. This research is aimed at improving our understanding and appreciation of complex systems in a way to guide the analytical tools and strategies that should accompany researchers when confronted with difference systems. The study concludes with a proposal for terminology to use in relation to different complex systems.

2 - Distributed Competence: How Team Structure Affects Task Performance

Martin Neumann

This paper is concerned with how different team structures affect task performance. By using a Case Study of the maintenance department of a large utility company as a starting point, the study creates an agent-based computational simulation model to compare four different structures: (a) strict hierarchy, (b) relaxed (or loose) hierarchy, (c) anarchy, and (d) hybrid (or baseline). The model is built by taking ethnographic observations from the Case Study to develop the basic layout for the model. The baseline case is the hybrid structure, from which the other structures have been created by reference to the literature. In accordance with the literature on distributed cognition in organizations, the main characteristic of the agents in the model is competence - i.e., their knowledge and practical expertise as they are functionally constituted

in relation to their taking on of tasks as well as their subsequent completion. The simulation reveals that the effect of competence changes depending on the network of relations (relationship range in the model) among employees allowed by the team structure as well as according to cognitive dispositions (docility in the model). These findings indicate that, despite an overwhelming individualistic characterization of competence, a more accurate representation would be for it to be considered distributed rather than solely attributable to the individual.

3 - When Reciprocity of Trust Backfires: Results of an Agent-based Simulation of Incomplete Incentive Contracts

Friederike Wall

Incentive contracts are a primary means to align subordinates' behavior with the organization's objectives. Among the difficulties incentive contracting encounters is measuring the performance in all task elements assigned to a subordinate, which may result in incomplete contracts. Then, mutual trust among the contracting parties is crucial: with an incomplete contract, the superior has some discretion over the subordinate's rewards. Hence, the subordinate's trust in the superior affects the willingness to incur effort related to the not-contracted task elements. On the other hand, the superior's trust in the subordinate is relevant to the rewards provided.

Building on Brower et al.'s (2000) theoretical model of trust in organizations, the paper translates the situation above of incomplete incentive contracts into an agent-based simulation model to study the emergence of reciprocal trust and the performance effects thereof.

The results suggest that neither the contracting parties' trust universally increases with the superior's propensity to reciprocate the perceived subordinates' trust, nor does performance generally increase with higher trust levels. Among the reasons is that the superior's trust in the subordinate might be "unjustified" from the subordinate's perspective. The results indicate that intra-organizational interdependencies, in conjunction with the superior's propensity to trust, subtly affect the trust-building of the contracting parties.

estimation problem is frequently non-unique although representative solutions have been used in the numerical experiments. In this presentation, we show first that the set of all rankings of alternatives under the estimated interval priority weights can be obtained easily. Using the set of all rankings in the numerical experiments, we confirm the advantages of several interval priority weight estimation methods.

2 - Stochastic Multicriteria Acceptability Analysis with Nonadditive Probability

Sally Giuseppe Arcidiacono, Salvatore Corrente, Salvatore Greco

We consider a nonadditive probability in the weight vector space considered by Stochastic Multicriteria Acceptability Analysis. We show that this allows us to represent uncertainty with respect to the weights to be assigned to the considered criteria as well as the Decision Maker's (DM's) optimism or pessimism in evaluating alternatives. After a motivating didactic example, we introduce our methodology, which is based on the definition of a nonadditive probability as a transformation of an additive probability in the weight vector space. To this end, we consider specific families of probability distributions and transformation functions discussing the results they provide, proposing also a methodology to induce them from DM's preference information. We discuss the results obtained through our methodology in the domain of composite indicators, considering an application in the framework of sustainable development of European Countries.

3 - A Seven-Valued Logic for Multicriteria Decision Aiding

Roman Slowinski, Salvatore Greco

In recent discussions on reasoning about data using the rough set concept, a class of many-valued logics has emerged to differentiate between vagueness resulting from imprecision and ambiguity arising from coarseness. These logics, including the renowned Belnap four-valued logic, stem from a comprehensive seven-valued logic framework. This study explores the application of the seven-valued logic and its derivatives in multicriteria decision aiding (MCDA). Specifically, we demonstrate how our approach effectively addresses common challenges in MCDA, such as uncertainty, imprecision, ill-determination, and related robustness concerns.

4 - XOR Numbers: Theory and Application

Amin Hocine, Sergio Ortobelli Lozza

We often find ourselves struggling to determine the truth, hesitating due to our ignorance. In such circumstances, the exclusive disjunction (XOR, for short) is commonly used to express our uncertainty, in contexts ranging from daily life, like "It was either Adam or John—but I couldn't determine which," to more professional scenarios, such as "Global growth is projected to be 3% in 2024, or it may weaken to 2.7% depending on prevailing economic conditions." The primary objective of this paper is to propose a framework to address the uncertainty inherent in such expressions by raising a pivotal inquiry: how to quantify this uncertainty without resorting to oversimplification that leads to the loss of crucial details essential for understanding the problem under consideration? Attempting to address this question leads to the concept of 'xoriness' and the 'XOR number.' In particular, xoriness is defined as a state of uncertainty stemming from hesitation, in which multiple objects (such as numbers in our context) are mutually exclusive, indeterminate, and none of them is dominating. This exploration proposes the 'XOR number' as an approach to quantify xoriness, recognizing that the multiple options itself represents a choice. This investigation extends to arithmetic operations, metric spaces, and the ordering of XOR numbers. Multiple criteria decision analysis is employed to demonstrate the applicability of the proposed framework.

1 - Comparing Interval Priority Estimation Methods by Estimation Accuracy of Solution Set in Terms of Ranking Alternatives

Masahiro Inuiguchi, Akiko Hayashi, Shigeaki Innan

The analytic hierarchy process (AHP) is a useful method for multiple criteria decision making. It provides a priority weight estimation method from a pairwise comparison matrix (PCM). A PCM evaluated by a decision maker (DM) is frequently inconsistent. The inconsistency is assumed to come from the evaluation errors. The priority weights have been estimated by minimizing the errors. However, human perception is vague. Assuming that the inconsistency comes from the vagueness, estimating interval propriety weights instead of crisp priority weights from a PCM was proposed. Many interval priority weight estimation methods have been proposed because the original interval priority weights estimation method tends to estimate insufficiently wide interval priority weights. Numerical experiments showed that ranking alternatives by interval priority weights estimated by several methods performs better than the crisp priority weights estimated by the conventional methods when we assume the DM's vague evaluation. It is shown that the solution to the interval priority weight

Chair: *Ruth Kaufman*

1 - Fast And Furious: Lightning Talks

Paul Bouman, Gökhan Ceyhan, Laura Albert, Hans Schwartzlose

At a conference like EURO, it is impossible to catch up with everything; and all too easy to stick to a single stream within your usual professional specialism. This session showcases some of the breadth of OR in action, with a set of twelve 5-minute presentations hand-picked to inspire, interest and extend your knowledge. The Fast and Furious session is always intense, enlightening and fun for audience and speakers alike, so a great way to start the conference.

Some of the presentations will be designed for this session only, others will be abbreviated versions of full talks appearing elsewhere in the conference. We are holding this session early on in the conference to give the audience the best chance of catching up with the speaker later on.

The talks cover a wide range of OR methodology across a great variety of practical application areas. Speakers include academics across the range from eminent to early career, as well as practitioners from a variety of industries.

The latest details of speakers can be found on the Making an Impact page on the main conference website (euro2024cph.dk/programme/making-an-impact-2024).

MCDA applications in Engineering and Management 1

Stream: Multiple Criteria Decision Analysis
Invited session

Chair: *Michalis Doumpos*

Chair: *Constantin Zopounidis*

1 - A Multicriteria Framework for Evaluating the Sustainability Performance of Local Governments: Application to French Municipalities

Michalis Doumpos, Alexis Guyot, Emiliós Galaríotís, Constantin Zopounidis

Sustainable development has become a central issue for policy decisions by governments and international organizations. The core framework of the UN's 2030 Agenda for Sustainable Development defines 17 Sustainable Development Goals (SDGs), which set the basis for operationalizing specific metrics to evaluate and monitor the actions and policies that countries take to balance social, economic, and environmental sustainability. Towards achieving the goals of the UN Agenda, the role of local governments is crucial. In this context, the objective of this study is to describe the development and implementation of a multicriteria framework for assessing the performance of local governments from the perspective of the UN's SDGs. The proposed framework is based on a comprehensive set of indicators that are aggregated through an outranking multicriteria decision aiding (MCDA) approach. The MCDA approach relies on a simulation process to consider the uncertainty and vagueness in the importance of the indicators across the various SDGs. Results are presented for a large sample of French municipalities, based on the most recent available data.

2 - Applying System Thinking Approaches for Supporting the Criteria Modelling Process in MCDA

Athanasios Spyridakos, Konstantina Theona

The criteria modelling stage of the MCDA approaches constitute fundamental and critical process for the effective implementation and supporting the decision making. The level of consistency of the criteria family affects the accuracy and reliability of the application of the methodological approach used and the final acceptance of the assessed preference model. This research work is focused on the application of system dynamics methodological tools for the analysis of the decision problem statement and the identification of the relative features in a detailed manner. The tools of the system thinking approach and the techniques of the archetypes are employed in order to picture the points of view of the decision problem, their interrelations as well as their impacts. Exploiting the analytical features of the above-mentioned tools a comprehensive and easy to use approach for the analysis and presentation of the decision problem is available. The methodology is illustrated through a case study concerning the location selection problem for the establishment of Educational Units.

3 - Classification of Students Based on the Risk of Dropping out of University Degrees

Marina Segura, Ana Maria Sanchez Sanchez, Adolfo Hernandez

Dropping out of university degrees is a problem with a considerable negative impact not only academically but also economically. The objective of this work is to design a multicriteria model that allows classifying students based on the risk of dropping out of the degree they are pursuing after the first year. Ordered categories of higher to lower risk are generated using the Global Local Net Flow Sorting (GLNF Sorting) algorithm, and the quality of student assignments to a risk group is evaluated using the Silhouette for Sorting (SILS) quality indicator. To quantify the risk of dropping out, criteria both before access to higher education and related to the context and results of students in the first semester have been used. The model is validated with real data from students in various degrees at Complutense University of Madrid. The obtained classification is compared with those obtained using traditional classification techniques and machine learning.

4 - A Multicriteria Model for Sustainable Customer Segmentation using a Sorting Outranking Method

Concepción Maroto, Ivan Felipe Barrera, Marina Segura, Baldomero Segura

Customer segmentation plays a key role in improving supply chain management by implementing appropriate marketing strategies. The objectives of this research are to design and validate a multicriteria model to support decision making for sustainable customer segmentation in a business to business context. First, the model based on the transactional customer behaviour is extended by a hierarchy with three main criteria: Recency, Frequency and Monetary (RFM), customer collaboration and growth rates. Customer collaboration includes quota compliance, variety of products and customer commitment to sustainability (reverse logistics and shared information). Second, the Global Local Net Flow Sorting (GLNF sorting) algorithm is implemented and validated using real company data to classify 8,157 customers of a multinational healthcare company. Third, the SILS quality indicator has been implemented and validated to assess the quality of preference-ordered customer groups. The results are also compared with an alternative model based on data mining (K-means). The multicriteria system proposed allows to segment thousands of customers in ordered categories by preferences according to company strategies. The segments generated are more homogeneous, robust and understandable by managers than those from alternative methods. These advantages represent a relevant contribution to automating supply chain management while providing detailed analysis tools for decision making.

DEA and its application

Stream: Data Envelopment Analysis and its Application
Invited session

Chair: Víctor Javier España

Chair: Ana Camanho

1 - Modeling Data Sovereignty in Public Cloud - A Comparison of Existing Solutions

Stanisław Galij, Grzegorz Pawlak, Sławomir Grzyb

Data sovereignty has long been a focal point for enterprise customers, cloud service providers (hyperscalers), end-users, and national and international policymakers. The cloud distributed computing model has been presented as a means to control and apply data sovereignty aspects. This presentation delivers a comprehensive review of data sovereignty aspects within the context of public cloud computing environments. While multiple technologies supporting data sovereignty in the public cloud already exist, they also impose certain limitations and increased costs due to the necessity of adhering to specific frameworks and leveraging additional cloud cryptography, thereby increasing computational overhead. This paper provides a comparison of reference architectures for solutions reflecting data sovereignty in the public cloud. Appropriate computational experiments were conducted, and conclusions have been formulated.

2 - DEA in Environmental Performance Evaluation for the Transport Sector: A Survey

Adel Hatamimarbini, Pegah Khoshnevis

The ITF Transport Outlook (2021) projects a 60% increase in carbon dioxide emissions (CO₂) by 2050, primarily from the transport sector. Emission reduction, crucial for sustainable development goals (SDG13), is emphasized by the UK Department for Business Energy & Industrial Strategy (2021) reporting a swift rise in CO₂ emissions from 97.7 MtCO₂ in 2020 to 107 MtCO₂ in 2021. Urgency is stressed by the UK Department of Transport (2021), urging a shift to a low-emission transport system with a 50% reduction by 2030. Despite this, EU transport strategies, as per the European Union's examples, have not effectively reduced CO₂ emissions. Researchers focus on methods like Data Envelopment Analysis (DEA) to assess transport performance, revealing a literature emphasis on road and passenger car CO₂ emissions. The study identifies gaps, suggests future directions, and recommends assessing maritime and aviation sectors.

3 - Measuring and managing (un)sustainable workload under digitization: A frontier-based job demands-resources model

Ahmed-Youssef Oukassou, Marijn Vershelde

In this paper, we bridge the psychological Job Demands & Resources (JD-R) literature with the operations literature on activity analysis. The JD-R model provides a comprehensive framework, categorizing risk factors associated with different occupations. On one hand, resources positively affect performance, while on the other hand, demands relate to work conditions. Understanding the health impairment process (strain due to excessive demands) and the motivational process (resource-driven well-being enhancement) is essential in defining a sustainable level of workload. We apply a multidimensional nonparametric activity analysis on the JD-R model, to assess the relation between resources, demands, and mental well-being of employees. Using event-level data of railway control room operators, we construct a multidimensional JDR indicator for digital production, which we empirically validate by using proxies for operational risk and employee well-being.

4 - Adaptive Constrained Enveloping Splines and Random Forest for Technical Efficiency Measurement

Víctor Javier España, Juan Aparicio, Josep Xavier Barber

In various research fields, understanding the relationship between predictors and a response variable involves curve estimation with specific characteristics. For instance, isotonic regression estimates mortality rates, assuming an increasing relationship between older age groups and mortality risk. Similarly, efficiency analysis can be reframed as a shape-restricted regression problem, aiming to estimate a non-decreasing and concave function that envelopes the observed data points. In this context, Data Envelopment Analysis (DEA) is commonly used for nonparametric production frontier estimation. However, DEA is susceptible to overfitting, resulting in overly optimistic efficiency estimates.

Recently, an adaptation of the Multivariate Adaptive Regression Splines (MARS) algorithm was introduced for production function estimation, addressing overfitting concerns. Our work builds upon this methodology, with three primary objectives. First, we propose a method to incorporate variable interaction during model fitting while maintaining shape constraints for production functions, enhancing predictive capacity. Second, we enhance robustness by randomizing data and input variables during model construction, drawing inspiration from the Random Forest (RF) methodology. Finally, within the RF framework, we can identify the most relevant inputs related to output prediction.

Lot-sizing with joint replenishment and routing decisions

Stream: Lot Sizing, Lot Scheduling and Production Planning
Invited session

Chair: Xinyi Ye

1 - Joint Replenishment and Heterogeneous Vehicle Routing Problem with Cyclical Schedule

Ming-Jong Yao, Chin Sum Shui, Chih-Han Wang

This study is based on a decision scenario of an industrial gas company that applies the Vendor Managed Inventory (VMI) model and supplies customers with liquid oxygen using a self-operated heterogeneous vehicle fleet. We name it a Joint Replenishment and Heterogeneous Vehicle Routing Problem with Cyclical Schedule. To solve this problem, we formulated it as a non-linear mixed-integer programming model that simultaneously determines the length of the planning cycle (PC), the length of the replenishment cycle, the dates to replenish each customer, and the vehicle routes of each day within PC, such that the average total cost within PC is minimized where the total cost includes inventory holding cost, setup cost, transportation cost, and overtime labor cost. We proposed a genetic algorithm (GA), which is embedded with an innovative encoding and decoding mechanism, local search operators, and a hash function to avoid repetitive fitness evaluation for identical solutions. Our numerical experiments demonstrate that the proposed GA can effectively solve the problem under different lengths of PC and number of customers. Also, when the demand of a customer increases, it can be applied to determine whether the company should expand the capacity of storage installed at the customer. Sensitivity analysis of the vehicle fleet composition showed that deploying a mixed fleet can reduce the average total cost.

2 - The Joint Replenishment Problem with Permissible Delay in Payments and Resource Constraints under Power-of-Two Policy

Jen-Yen Lin

The Jointly Replenishment Problem (JRP) is concerned with determining lot sizes and scheduling replenishment times for n products to minimize total costs per unit time. In practice, consolidating replenishments to share common setup costs is crucial. Additionally, researchers often introduce constraints to enhance the applicability of inventory systems. Examples include the adoption of a power-of-two (PoT) policy for streamlined scheduling, imposing minimum order quantities for commitment, and enforcing maximum shipment sizes based on capacity constraints.

In this paper, we explore JRP models incorporating the PoT policy and bounds for replenishment time. We provide a theoretical analysis of these models, propose a search algorithm to identify global optimal solutions, analyze the complexity of the algorithm, and conduct randomized experiments to validate our approach.

By addressing these issues, our work contributes to the advancement of JRP models, offering practical insights and solutions that accommodate real-world constraints and enhance operational efficiency.

3 - On Static and Dynamic Inventory Rebalancing in Bike Sharing

Haoxiang Wang, Dimitrios Letsios, Xinyi Ye

We elaborate on inventory rebalancing in bike sharing. The goal is to decide how to reposition bikes between the stations of a bike sharing network so as to optimize service loss, based on the dynamic lot sizing model. Previous work computationally demonstrates the benefits of dynamic compared to static rebalancing. We propose new optimal algorithms for both problem variants. On the negative side, we show that static rebalancing results in $O(1/\epsilon)$ proportion of successful requests. On the positive side, we prove that dynamic rebalancing achieves an $\Omega(1-\epsilon)$ performance guarantee. To our knowledge, this is the first theoretical characterization of the dynamic rebalancing benefits compared to static rebalancing. Next, we consider the more general problem of optimizing service loss with bounded rebalancing costs. For both the static and dynamic variants, we develop new scalable mixed-integer approaches to practically relevant instances. We computationally substantiate the proposed approaches using data from the London bike sharing network.

4 - Optimizing the Work-in-Progress Area Allocation of pallet-like production process: A Mixed-Integer Linear Programming Approach

Katharina Eibler

An efficient allocation of space in Work-in-Progress (WIP) areas is a key factor for a smooth flow in production, as inadequate planning can lead to bottlenecks, machine idle time and delays. This is especially critical in situations of a high occupation rate as well as limited space. We present an optimization approach for pallet-like production processes illustrated by the working flow in a plant. Our approach is based on mixed-integer linear programming (MILP) and the model allocates order blocks to lanes of varying sizes, while considering the production plan of machines before and after the WIP areas, coupling possibilities of lanes as well as different sequence requirements on lanes. The allocation is optimized according to plant-specific needs, including suitability of the lanes for the orders, lanes kept free for potential changes and blocks of the same order being assigned near each other. We illustrate our approach using synthetic data to mimic the production process of a real plant.

1 - The Impact of Customer Picking on Retail Food Waste

Alexander Hübner, Fabian Schäfer, Tobias Winkler, Kai Hoberg

This paper investigates the impact of customer withdrawal on retail food waste. Customer picking for the freshest items (called last-in-first withdrawal) leaves products with shorter expiration dates on the shelves. However, currently applied barcodes do not include the expiration date. We partnered with a retailer to collect missing expiration data. We implemented a process adaption in a pilot warehouse and develop a novel method to quantify waste caused by customer picking in panel data. Our findings show that, on average, 45% of the food waste in our sample is caused by customer picking. Building on the results of the customer picking waste quantification, an exploratory approach is applied to identify product and store-related drivers.

2 - Quantifying the potential to reduce food waste and increase freshness in a two-echelon divergent single product supply chain.

Rob Broekmeulen, Karel van Donselaar

Our study investigates allocation strategies at a retailer warehouse that replenishes a multi-period perishable product in case packs to a set of different stores that face stochastic demand. The objective of the retail chain is to reduce food waste and increase freshness, while maintaining an agreed service level in the stores. Since the warehouse has a high service level target for replenishing the stores, it has to keep safety stock, which results in batches with different ages at the warehouse. We showed in a previous study that the waste at the stores can be significantly reduced by unpacking the case packs at the warehouse and/or increasing the remaining shelf life, especially for stores with a low demand. Unpacking at the warehouse allows the stores to order in smaller quantities, but this increases the order picking costs for the warehouse. We quantified in our new research the potential improvements of allocating only a fraction of the stores with unpacked and/or fresher products to limit the additional supply chain costs resulting from applying these strategies.

3 - Dynamic pricing strategy for substitute perishable products

Mariana Sousa, Sara Martins, Maria João Martins dos Santos, Pedro Amorim

Dynamic pricing is a widely used strategy for adjusting the price of goods and services in response to changing and demanding consumer behavior. In grocery retailing, this approach is often applied to perishable products to encourage consumers to purchase items with limited remaining shelf life. However, existing pricing strategies often overlook the impact of sales cannibalization among similar products and lack differentiation in discounts across the product spectrum. In this study, we develop a dynamic pricing approach for a variety of perishable items with a focus on optimizing retail profits and reducing food waste. We first test assumptions about substitution effects among similar products using historical data from a European retailer. We then develop a demand forecasting model for a subset of the products and incorporate it into a reinforcement learning algorithm. This algorithm determines the pricing strategy for the selected set of products, establishing continuous discounts throughout their shelf life. Finally, we analyze the impact of considering multiple products rather than a single product at a time to develop the pricing policy. This research provides insights into a methodology for constructing dynamic pricing strategies and uncovers practical implications.

4 - Optimizing assortments with age-dependent inventory

Manuel Ostermeier, Alexander Hübner, Lena Riesenegger

Determining the assortment and inventory levels based on their shelf life is essential for retailers to maximize profits while avoiding food waste. The limited shelf space and the handling of perishable products with limited shelf lives interrelate assortment and inventory decisions. A joint approach is needed that defines the assortment size and the maximum possible inventory levels while considering differing product ages and their implications on the planning. The product ages on the shelves are further impacted by the customers' withdrawal behavior. For instance, customers intentionally selecting products with longer expiration dates change the order of depletion as older products are left on the shelf. These interferences need to be considered when

Food Waste

Stream: Retail Operations

Invited session

Chair: Manuel Ostermeier

deciding on the products within the assortment and their corresponding inventory levels. We develop the first multi-period approach to address the interrelation between assortment planning and inventory management by integrating product shelf life and outdated. The resulting planning problem is solved using an iterative approach that considers different customer withdrawal behaviors and established demand effects.

1 - Firm Zombification & Corporate Policy: Empirical examination of Indian Firms

S Yesaswi Dora, Ajay Kumar Mishra

This study addresses the escalating concern of zombie firms in the Indian context, employing a unique methodology to identify and analyze their characteristics. Utilizing a dataset encompassing 45,867 firm-year observations from 2009-2021, our approach identifies 1,199 zombie firms, comprising 29.35% of the sample. Regression analysis reveals a positive link between high reliance on debt capital and the likelihood of zombification. These firms exhibit characteristics such as being relatively new, possessing small asset sizes, higher leverage, and poor performance. Additionally, they maintain lower cash holdings, higher leverage ratios, and lower capital intensity. Our findings indicate that zombie firms adopt a conservative cash policy and aggressive financing, coupled with a conservative investment approach. This study contributes to the existing literature, shedding light on the implications of zombification for corporate policies in the Indian business landscape. The research emphasizes the potential misallocation of funds, posing a financial burden for both companies and the economy. As the first of its kind in the Indian context, this study holds critical implications for corporates, creditors, and policymakers, providing valuable insights for enhancing economic well-being and long-term viability.

2 - Robust Asset Liquidation Strategies in Financial Systems

Hongyi Jiang, Dohyun Ahn

In this paper, we study the problem of liquidation strategies in financial networks over two periods. Financial contagion arises when substantial overlapping illiquid assets are sold at significantly depressed prices. We present a novel strategic liquidation model for a bank in financial networks, allowing for preemptive liquidation before maturity, where the uncertainty of other banks' two-period liquidation decisions poses a challenge to risk evaluation. To address the issue, we propose a robust quantification for the liquidation income and develop the optimal liquidation strategy for maximizing the bank's cash after liquidation under the worst-case scenario, which we refer to as the 'maximin strategy.' We prove that the maximin strategy is unique and remains invariant in the presence of interbank liabilities. We further demonstrate that with the information on all banks' liquidation strategies available, the strategic liquidation problem becomes a liquidation game whose unique Nash equilibrium is that all banks adopt their maximin strategy. In addition, with only aggregate information on interbank liabilities, we provide a modified near-optimal strategy for weakly interconnected financial networks. Our results provide guidelines for developing robust liquidation strategies that alleviate losses from financial contagion and build insights into evaluating liquidation effects in the financial network for decision-makers.

3 - Portfolio selection with two risk sources and inverse optimization

Hanna Zhurba, Sergio Ortobelli Lozza

In this work, we first discuss how evaluating two sources of risk (market risk and trend risk) using a unique measure of risk. In particular, we combine two risk measures with alternative correlation matrix in order to get a unique risk measure. Then we extend the inverse optimization problem proposed by Black and Litterman (1992) adapted to this context. Finally, we propose an ex post empirical analysis, where we compare the proposed models with other different portfolio selection models.

4 - Return and volatility spillover among the global private equity markets

Antonio Díaz, Carlos Esparcia Sanchís, Lars Tegtmeier

This study investigates return and volatility spillovers between different regional private equity markets and investment styles to analyze the dynamics of interconnectedness. This is done using the LPX Group's listed private equity indices for the period January 2004 to September 2023. The results show that the LPX America index is a net transmitter for the LPX Europe index. The transmission of volatility spillovers from the US to Europe precedes the impact of return spillovers by several months. Furthermore, Europe only becomes a transmitter for the US in a few specific European events. For the investment style indices, the LPX Buyout index consistently acts as a net return spillover transmitter throughout the sample period, while the LPX Mezzanine index consistently exhibits higher net volatility spillovers. The LPX Venture index consistently acts as a net receiver. The catalysts for risk contagion within the LPX indices are explicitly stated to be the differential impact of major economic and financial events. Another reason for the observed spillover effects could be herd behavior as a transmission channel.

Combinatorial optimization approaches for freight deliveries and home services

Stream: Combinatorial Optimization

Invited session

Chair: Claudia Archetti

1 - A Triple Bottom Line optimization model for assignment and routing of on-demand home services

Debajyoti Biswas, Laurent Alfandari, Claudia Archetti

In this paper, we study the assignment and routing of service professionals for serving customers of an on-demand home services platform considering the Triple Bottom Line (TBL) criteria for ensuring sustainability in operations. We characterise this as the Home Services Assignment and Routing Problem with the Triple Bottom Line (HSARP-TBL) and implement a Mixed Integer Linear Programming (MILP) model for solving it. We assign service professionals to customers based on their desired time slots and also transport modes for each customer visit by a professional, considering either combinations of public transport or a personal vehicle for each professional's tour. The objective is to minimize costs due to time window violations and uncovered customers, catering to the economic pillar of the TBL. We incorporate additional constraints based on the TBL by - improving customer satisfaction based on the ratings of assigned professionals to customers, with and without subscription (economic), controlling emissions due to transportation of professionals (environmental) and ensuring equity in service allocation and net earnings between professionals (social). For tackling large instances we implement a Hybrid Genetic Search (HGS) algorithm adapting it to our problem setting. We demonstrate that the HGS outperforms the MILP model systematically for large instances in terms of solution value and computational time.

2 - Stochastic Scheduling and Routing Decisions in Online Meal Delivery Platforms with Mixed Force

Claudia Archetti, Laurent Alfandari, Yanlu Zhao

This paper investigates stochastic scheduling and routing problems in the online meal delivery (OMD) service. The huge increase in meal delivery demand requires the service providers to construct a highly efficient logistics network to deal with a large-volume of time-sensitive and fluctuating fulfillment, often using inhouse and crowd-sourced drivers to secure the ambitious service quality. We aim to address the problem of developing an effective scheduling and routing policy that can handle real-life situations. To this end, we first model the dynamic problem as a Markov Decision Process (MDP) and analyze the structural properties of the optimal policy. Then we propose four integrated approaches to solve the operational level scheduling and routing problem. In addition, we provide a continuous approximation formula to estimate the bounds of required fleet size for the inhouse drivers. Numerical experiments based on a real dataset show the effectiveness of the proposed solution approaches. We also obtain several managerial insights that can help decision makers in solving similar resource allocation problems in real-time.

3 - Dynamic programming state space restrictions to solve the joint order batching and picker routing problem via column generation

Maxime Ogier, Hadrien Cambazard, Nicolas Catusse

We address the joint order batching and picker routing problem (JOBPRP). Given a set of orders to collect, each order being composed of several items located in a warehouse, the JOBPRP consists in batching orders into capacitated trolleys such that the total travelled distance to collect all the items of the orders is minimized.

We are interested in algorithms based on column generation. A bottleneck of such approaches is to efficiently solve the pricing problem, that is a profitable order picking problem where all products of an order must be collected together in the same tour and a price is gained for collecting an order. At the core of this pricing problem lies a profitable traveling salesman problem (TSP) in a rectangular warehouse. Dynamic programming (DP) approaches can solve efficiently this TSP for such layouts.

In this work, we extend the DP approach to the profitable variant. The directed acyclic graph underlying the DP can be used to provide a powerful Mixed Integer Programming (MIP) formulation where the order requirements (all products of an order must be collected together) can be taken into account with linking constraints. Such MIP formulation has been studied for the special case of warehouses with a single bloc of aisles. We generalize to the case with several blocks, and propose state space restrictions of the DP to heuristically solve the pricing problem.

The proposed approach is validated on instances from the literature.

dispatchers are tasked with adjusting the rolling stock schedule. In this paper, we develop a rolling stock rescheduling method which ensures feasibility with respect to the availability of the railway infrastructure. In particular, we explore the option of performing shunting movements at stations where shunting is not allowed in current practice, due to the large number of trains that pass through or due to the complexity of the station layout. We introduce an iterative rolling stock rescheduling algorithm which alternates between two mathematical formulations, namely one that creates an interim rolling stock schedule and one that tries to fit the suggested shunting movements between the remaining railway traffic. We test our solution approach with instances that contain complete railway blockages on the Dutch railway network. We allow for shunting at some of the busiest stations in the country and model the infrastructure of these stations to evaluate the feasibility of the suggested shunting movements. Our algorithm succeeds in adjusting the rolling stock schedule within running times of around a few minutes. We successfully identify feasible shunting movements and therefore improve upon the rolling stock schedule that would otherwise be obtained if performing shunting movements at the considered stations is prohibited.

2 - Extension to RECIFE-MILP Train Rescheduling

Valentina Cacchiani, Andrea Bettinelli

Real-time Train Rescheduling is applied to obtain a new feasible schedule when unexpected delays occur causing train conflicts and delay propagation. Train Rescheduling consists of train reordering, re-timing, and rerouting. We consider the well-established approach for Train Rescheduling, called RECIFE-MILP: it consists of first solving a microscopic Mixed Integer Linear Programming (MILP) model within a given time limit by neglecting train rerouting and then solving the complete model with the computed solution as a warm-start.

In this work, we extend RECIFE-MILP by including additional constraints on (mandatory or soft) train connections and restrictions on the access or speed to utilize the available infrastructure resources, and an objective function that penalizes, through a step-function, trains arriving late or early and differences from the desired travel time, the use of detours, and the violation of soft train connections. Computational results are reported on realistic instances to show the performance of the proposed approach.

3 - Robust Rolling Stock Rescheduling

Evelien van der Hurk

In railway planning, effective disruption management tools are necessary to limit the impact of a disruption. The duration of a disruption plays a central role in this process and is typically assumed to be known with certainty. However, in practice the duration is uncertain, and neglecting this aspect may lead to inefficiencies. We propose two different approaches for incorporating robustness when rescheduling rolling stock units while considering a disruption of uncertain duration. The first, termed strict composition robustness, obtains a schedule that is feasible for all possible realizations of the disruption duration and, therefore, can be easily modified in the case that the disruption lasts longer than expected. The second, termed light trip robustness, focuses on the notion of "trip robustness", and requires that out of a set of critical trips a pre-specified percentage should be robust with respect to their incoming composition across different disruption durations. We propose extensions of a well-known rolling stock scheduling model to respectively capture the different robustness criteria and, on a diverse set of real-life instances from the Dutch railway network, compare their performance to a naive approach that assumes a given disruption duration. The results show that all methods are worthwhile and that the choice of which to apply is highly dependent on the likelihood that the disruption will last longer than anticipated.

4 - A Heuristic Approach for Real-Time Adjustment of Disruption Programs - Applied to the Context of Commuter Railway Systems

Cedric Steinbach

Disruption on commuter railway systems with significant capacity restrictions (e.g. line closures) lead to substantial effects on the planned operations. One strategy to manage occurred disruptions is based on the use of pre-structured operating concepts, prepared to deal with generic disruption scenarios, so-called disruption programs (DRP). Since DRPs are planned offline for specific scenarios (e.g. failure of

1 - An Iterative Framework for Rolling Stock Rescheduling with Railway Infrastructure Availability Constraints

Jia Hui Zhu, Twan Dollevoet, Dennis Huisman

Disruptions on the railway network lead to reduced availability of the railway infrastructure. In the face of such disruptions, rolling stock

a certain group of infrastructure elements, like signal boxes), they allow dispatchers to react more effectively to the occurred event. If a disruption affects a combination of infrastructure elements that are not explicitly considered within an existing DRP, the full potential of the DRP cannot be utilized. To support dispatchers in responding to disruptions, an ad-hoc adjustment of the DRPs to the availability of the infrastructure has been developed. The approach determines the need, develops and introduces necessary adjustments to existing DRPs. At its core, the adjustment is a problem of combinatorial optimization, which is solved using a heuristic method. By combining components of different metaheuristics, a problem-specific solution approach based on a local search was developed. The approach assesses the adjustments based on their impact on the resistance of the passengers' connections and ensures the operational feasibility of the adjusted DRP. To illustrate the approach, it is applied to an example of a disruption in a commuter railway system

Transportation Network Modelling and Optimization I

Stream: Transportation

Invited session

Chair: Natsumi Takahashi

1 - A Queueing-based Throughput Analysis of the Mixed Traffic with Autonomous Vehicles

Xiangdong Chen, Hao Guan, Qiang Meng

In recent years, the automotive industry and transportation systems have seen a remarkable surge in the development of autonomous vehicles (AVs), driven by advancements in automation and vehicle-to-everything (V2X) communication technologies. In the foreseeable future, when AVs come into our society, it is evident that semi-AVs will continue to play a predominant role in the market due to safety concerns and cost considerations. This study aims to provide models to derive and analyze the throughput and travel time of the transitional mixed traffic with semi- and fully-AVs. To accurately capture the dynamics of different platooning behaviors of fully- and semi-AVs and their impact on travel efficiency, we employ a Markov chain model to derive headway distributions under varying traffic densities, and integrate the Markov chain with a state-dependent queueing model to characterize the mixed traffic flow. The derived mean headways are then utilized to compute the service rate of a state-dependent queueing system, enabling the calculation of long-term throughput and mean travel time through a highway segment. This study reinforces the research on transitional stages of mixed traffic with semi-AVs, revealing the potential for semi-AVs to enhance traffic efficiency. Moreover, it provides valuable insights for the development of management and control strategies in the transitional mixed traffic stages, guiding future designs and implementations.

2 - An active learning-based optimization for road traffic networks with uncertain service

Suh-Wen Chiou

For a road traffic network with uncertain service, a learning-based optimization is presented. In order to appropriately address spatial evolution of traffic congestion inside road links, a time-varying traffic model with uncertain capacity at links downstream is considered. Accounting for road users' behavior, a learning-based bilevel program can be proposed. A learning-based optimal signal settings can be determined at the upper level via reinforcement learning and users' equilibrium traffic flow can be decided at the lower level. In order to effectively solve the proposed bilevel program, a learning-based optimization can be decomposed into two sub-problems. A Quasi-Newton update is introduced to find solution with globally asymptotical convergence. In

order to ensure feasibility of solution found against high-consequence realization of stochastic capacity, a learning-based robust model is proposed. Numerical experiments are performed at a moderate traffic grid. As compared to conventional approach, obtained results obviously showed that the proposed model can exhibit sufficient gain of achieving effectiveness while attenuating time-varying congestion in the presence of stochastic capacity at links downstream.

3 - A link-based traffic equilibrium model for multi-modal network

Weizhao Su, Selin Ahipasaoglu, Edilson Arruda

This study introduces a link-based traffic assignment and equilibrium model for multi-modal networks considering congestion effects on travel times. To seamlessly enable the mode switch at any step of the journey, we employ an intervention control modelling technique that utilizes a multi-layer network wherein each layer corresponds to a feasible mode choice. The approach also enables us to prescribe node-dependent mode switching costs. The solution technique relies on dynamic programming and allows us to implicitly consider all possible route and mode choice combinations without enumerating all of them explicitly. This model can be used to design, analyze, and operate transportation systems that include multiple modes such as a variety of sustainable options.

4 - Exploring Strategy for Stochastic Maximum Flow Network Interdiction Problem

Natsumi Takahashi, Tetsushi Yuge

In this paper, we consider the network interdiction problem using the network flow as the performance measure. An evader wishes to maximize the expected flow of some illegal commodities such as drugs without being detected. On the other hand, a defender aims to minimize the objective of the evader by interdiction activities, such as adding some security controls, that can alter the probability measures. In this study, flows are intercepted stochastically at each arc, and the expected flow is calculated by considering the penalty cost when the network flow is detected. We need to determine which path from the source to the sink in the network can most effectively maximize the expected flow considering the detection probability, and to determine which arc is the best to interdict. To minimize flow, the defender increases the detection probabilities of arc with a cost by interdiction activities. Under the total interdiction cost constraint, whether each arc is to be interdicted or not is the decision to be made. This paper proposes an efficient search method for optimal interdicted arcs in such situations.

1 - Characterizing last-mile freight transport using mobile phone data: The case of Santiago, Chile

Raul Pezoa

Understanding the mobility of ground freight transport is critical in urban planning and for developing public policies. Literature shows that most of the previous studies on this topic rely on surveys and limited data, hindering the accuracy of the analysis. To cope with this drawback, in this paper, we present an innovative methodology for characterizing last-mile freight transport that uses a novel data source: mobile phone data, which offers the advantage of a broader coverage compared to data sources used in previous contributions. To the best of our knowledge, no prior articles have employed mobile phone data sources to study freight transport. To bridge this gap, we propose a methodology that calibrates supervised machine learning models to determine which cell phones correspond to truck drivers. To do so, we construct

input variables that seek to track the daily movement patterns of mobile phones, including traveled distances, interactions with highway networks, and land use variables. We test our approach by conducting a case study in Santiago, Chile, for which we analyze mobility patterns and logistic indicators disaggregated by day, hour, and zoning. Our results show high activity in Santiago's outskirts, especially in the northwest and southwest areas, with many interactions due to logistic centers and industrial zones. Similarly, central and eastern Santiago also show high stop density, reflecting intense commercial activity.

2 - A Real-Life Order Allocation and Dispatching Problem in Megacities

Muchammad Arya Zamal, Albert Schrottenboer, Tom van Woensel

This study addresses the complexities of two-echelon distribution systems in modern city logistics, highlighting the challenges faced by megacities like Jakarta, Indonesia. In collaboration with an industry partner, our research explores a logistics platform designed for efficient same- and next-day deliveries between local shops and consumers. In this context, we introduce the stochastic and dynamic order allocation and dispatching problem (SDOA-DP) aimed at minimizing costs by optimizing order allocations to linehauls between two-echelon systems and dispatching strategies within them. This paper makes the following contribution: advancing corridor-based logistics by explicitly integrating efficient linehaul planning with first and last-mile routing, employing a cost-function approximation within a two-stage stochastic programming formulation for dynamic order assignment, and leveraging a parameterized Adaptive Large Neighborhood Search algorithm for routing. Finally, our model was implemented using real-life data, demonstrating the approach's effectiveness in reducing logistics costs.

3 - Sharing e-bikes between multiple depots

Dmitry Krushinsky

Electric bikes have their niche in the last mile logistics. They offer certain advantages in terms of reduced emissions and infrastructure congestion. Sharing bikes between multiple depots provides for extra route flexibility and improved performance of the logistics system. In this talk, we address route optimisation for electric bikes in a shared multi-depot setting. We discuss modelling issues and present insights from computational experiments a.o. on the interplay between the locations of the depots and the performance of the transportation system.

4 - Modelling and optimization of a two-echelon last mile urban freight distribution system.

Alessandro Farina, Daniele Conte, Giada Marconi, Marino Lupi

In this paper, a new methodology for the modelling and optimization of a two-echelon last mile freight transport system for urban areas is proposed. Last mile deliveries are managed by means of an UDC (Urban Distribution Centre) located on the border of the urban area. At the UDC, freight is consolidated on small load units, for example pallets or small swap bodies, that are loaded on train wagons. Freight is then transported by train to some places on the border of the city centre, namely cross-docking points, where it is transhipped to small electric vans that carry out the last mile distribution. This problem has been addressed as a two-echelon urban freight distribution system with fixed satellites, where the UDC plays the role of the depot and cross-docking points play the role of satellites. A micro simulator has been developed to represent the second by second activity of each vehicle, of each train, and of each load unit. The micro simulator represents: the last part of the delivery trips, from cross docking points to receivers, but also the part of delivery trip carried out by train and the transhipment operations at cross-docking points. The simulator embeds a genetic algorithm that optimizes the vehicle routes from cross docking points (satellites) to final receivers. The proposed transport system has been applied in simulation to the city of Livorno, Tuscany, Italy.

Modelling commodity markets dynamics

Stream: Modern Decision Making in Finance and Insurance

Invited session

Chair: *Lorenz Schneider*

1 - Assessing the Profitability of Large-Scale Batteries in the UK Electricity Market

Nina Lange, Stefan Ropke

The transition towards an electricity market with a high penetration of renewable energy is characterized by higher price volatility compared to the more traditional electricity market dominated by conventional generation. The increasing share of intermittent generation requires a method of securing supply and matching demand with supply. Integrating batteries as fully controllable energy storage into the system is a solution to handling this issue. The inclusion and operation of batteries can contribute to the green transition if market participants can operate them profitably. This project aims to quantify these batteries' economic viability, increasing their incentive to be invested in and participate in the electricity markets.

In this paper, we run an optimization model based on forecasts of electricity prices in the day-ahead and in the intraday market. The model's performance relies on forecasts of the electricity prices.

We compute the profit from operating the batteries according to our algorithm during 2020 and 2021 in the UK electricity market. The chosen forecast methods can obtain profits in the range of 30-40% compared to the profit generated from perfect foresight of price developments, i.e., supplying the models with realized prices. In addition, we investigate how participating in both the day-ahead and the intraday markets yields superior results compared to focusing on just one of the markets.

2 - Commodity Forward Curves with Stochastic Time Change

Maren Diane Schmeck

Using powerful technique of stochastic time change, we introduce a new two-factor commodity price model, where one of the fundamental factors is the activity rate. This factor implicitly introduces stochastic volatility into the model. The model is developed under both physical and risk neutral probability measures, which allows for a wide range of applications ranging from derivatives pricing to risk management. We derive forward prices and forward curve evolution within the model's framework and develop an ingenious calibration procedure, which allows us to filter out the activity rate from daily observed price data. We apply the model to the rich dataset of daily crude oil and natural gas spot and futures prices and demonstrate its versatility and excellent fit to the historical forward curves

3 - Calendar Spread Options and the Term Structure of Volatility

Malthe Rauh Johansen, Nina Lange

We introduce a multi-factor stochastic volatility model aimed at describing the combined dynamics of both futures and option prices in commodity markets. The model is arithmetic, meaning that futures prices are affine functions of a finite set of state variables, which allows us to derive tractable formulas for vanilla options, and importantly, also for spread options. This dual tractability is a distinguishing feature of arithmetic models when compared to their multiplicate counterparts, and makes the model parameters amenable to efficient estimation using the Kalman filtering methodology on time series data consisting of futures and both types of options.

As an empirical application of the model, we apply the unscented Kalman filter on a data panel consisting of WTI crude oil futures, vanilla options, and calendar spread options. We demonstrate that the

model can achieve a good fit to the data and describe how the inclusion of calendar spread options in the estimation provides additional information on the term structure of volatility and correlation.

4 - Revisiting the Gibson-Schwartz and Schwartz-Smith Commodity Models

Lorenz Schneider, Bertrand Tavin

We extend the Gibson-Schwartz (1990) and Schwartz-Smith (2000) models to include stochastic volatility and correlation based on the generalized Wishart variance-covariance matrix process. We study European option pricing via characteristic functions. Furthermore, we perform parameter estimation via maximum likelihood based on the state space formulation of the models.

Automated Timetabling

Stream: Automated Timetabling

Invited session

Chair: João Almeida

1 - Service-oriented approaches to automated timetabling

Alexander Kuckelberg

The optimal creation of timetables under various aspects is a topic in many research and implementation projects. Various procedures and mathematical approaches are used as well as modelling, target functions and perspectives. For example, timetables can be optimized from a railway undertaking's perspective in terms of resource and circulation planning, from an infrastructure operator's perspective focussing capacity perspective, or from a transport association's perspective from traffic and stream considerations. On European main railways, it became practice for a separated, independent company - usually infrastructure manager - to be responsible for coordinating and synchronizing the various requirements and wishes of the various parties involved and bringing them together into a common timetable. The timetable processes are generally subject to predetermined agendas, phases and conditions, e.g. early route registrations, international traffic, route prices and priorities, framework agreements, etc. As a practical report, the article presents an approach to making this timetable planning process available as a usable IT service through a service interface and gives a brief insight into the scenarios, usages and working methods as well as results of such service components and organizes them into the practical process and the framework conditions of practice-relevant systems automated timetable planning.

2 - Analyzing the impact of operational disruptions on airline ground staff planning

Mahekha Dahanayaka, Dennis Prak, Rohit Gupta, Martijn Mes

Staff planning for airport ground operations usually starts well ahead of the day of operation. Aircraft delays, caused by factors such as weather and technical issues, subsequent cascading delays on the ground, as well as workforce uncertainties, are all unknown at the moment that staff plans are made and are typically disregarded. In practice, airlines have traditionally prioritized equipment over staff as the primary constraint, thus devoting less attention to the latter. Moreover, the computational complexity associated with staff shift planning problems has led the prevailing approach to be deterministic, assuming complete knowledge of the specific tasks and their respective timings. However, recently, the labour market has tightened significantly, causing a focal shift toward staffing constraints. In this study, we explore the impact of uncertainty on schedule performance, drawing inspiration from the practical operations of a major European hub-and spoke carrier, with a particular focus on the planning of baggage (un)loading staff. We simulate disruptions and the consequent recovery strategies using

historical data to demonstrate the quality of priori decisions regarding shift and break timing, staff allocation, and long-term workforce planning. Based on this, we offer insights into the significance of diverse uncertainty types, their magnitudes, and correlations, demonstrating how planning decisions can be adjusted without sacrificing computational tractability.

3 - Using predictions on employee absenteeism to generate robust personnel rosters

Pieter Smet, Martina Doneda, Giuliana Carello, Ettore Lanzarone, Greet Vanden Berghe

Employee absenteeism occurs when an employee is not present at work during their scheduled hours. When this situation occurs, the absent employee's shift must be covered by another employee. This in turn may affect others in the organisation, creating an undesirable ripple effect that can propagate throughout the entire roster. Generating robust personnel rosters can proactively mitigate the negative consequences when employees are absent from work. One way of increasing roster robustness is by scheduling special on-call duties that can be converted into regular working duties whenever necessary. Machine learning models that predict when employee absences will occur provide an intuitive and regularly employed approach to determine where best to position on-call duties in a roster. In this talk we will propose a methodology to evaluate the circumstances under which such predictions can actually increase roster robustness. More specifically, we will analyze the results of a series of computational experiments to determine the prediction performance levels needed by a machine learning model to outperform a non-data-driven robust rostering method.

4 - A hybrid meta-heuristic for the generation of feasible large-scale course timetables using instance decomposition

João Almeida, José Rui Figueira, Daniel Santos

We propose a hybrid meta-heuristic for generating feasible course timetables for large-scale problems. A novel instance decomposition technique is introduced. Different types of constraint violations are regarded as objective functions to be minimised. The search targets slots where the most violations are identified. After some iterations without improvements, the most challenging constraint groups are given new weights, guiding the search towards non-dominated solutions, which improve the performance of these objectives, even if the total sum of the violations increases. If this mechanism fails to escape these local optima, a shaking phase is conducted. The decomposition mechanism operates as follows: curricula are iteratively introduced to the problem, and new feasible solutions are found considering the increasing set of lectures. The assignments from each iteration can be modified in subsequent iterations. We tested real-world instances from our university and random sub-divisions. For sub-divisions with 400 curricula, decomposition reduces the solution times to up to 27%. For real-world instances, with 1288 curricula, the reduction is 18%. Clustering curricula with common characteristics when incrementing the instances improved the solution times by 18% more than random increments. Feasible solutions for the real-world instance are found in 21 minutes, whereas the commercial software takes several hours, and can fail to comply with some constraints.

1 - Advertising by Recruiting Influencers

Maya Jalloul, Vasiliki Kostami

The growth of social media platforms allowed customers to rely on influencers and past consumers' experiences for their purchase decisions. In this paper, we address some of the firm's challenges of influencer marketing by considering different types of influencers and partnership schemes with them and we address the effect of social learning. We introduce a two-period model. In the first period, the firm launches a new product and an influencer marketing campaign. The campaign can rely on two types of influencers that differ in popularity and credibility and two potential partnerships; sponsored advertising and public relations. Customers make their purchase decisions using their original beliefs, the information obtained via the influencers they follow, and reviews of early adopters as they become available in the second period. When customers are equally likely to follow the same influencer, the firm should partner with a single influencer type through a single type of partnership. Furthermore, social learning is highly beneficial for an undervalued product when supplemented by advertising. Finally, in a society formed by classes where followers and influencers usually belong to the same class, a diverse mix of influencer advertising methods can be optimal. We suggest the strategic partnerships a firm should establish with social media influencers depending on their credibility and popularity, the market composition, and the characteristics of the social media platform.

2 - The Power of Perceived Value and Transformative Pricing in Online Food Delivery Platforms

Arvind Shroff, Bhavin Shah

Currently, Online Food Delivery (OFD) platforms like DoorDash, Zomato and UberEats dictate the delivery fee charged to customers for orders placed through them. This delivery fee is based on the order value and the distance traveled by the driver to complete the delivery. Pay-As-Asked (PAA) delivery pricing strategy is the name of this tactic. On the contrary, Pay-What-You-Want (PWYW) is an innovative pricing strategy that gives customers the final say over the price they are willing to pay based on how valuable they perceive the service. To investigate how the adoption of pay-what-you-want (PWYW) for delivery fee pricing affects the financial viability of OFD platforms, we present an analytical model. By dividing consumers into three groups—free riders, fair-minded consumers, and generous consumers—we are able to identify their social preferences for things like fairness and reciprocity. This allows us to determine the conditions under which PWYW might be more profitable for the platform than the typical PAA delivery pricing strategy. Our research suggests that to maximize platform profits when implementing a PWYW delivery fee, the OFD platform managers should work to reduce delivery costs as much as they can. Furthermore, we propose that platforms impose a minimum delivery fee that customers may use as a guideline when determining the fee they want to pay to prevent free riders from reducing profits under PWYW.

3 - Disruption Mitigation and Pricing Flexibility

Oben Ceryan, Florian Lückner

We study how a firm's pricing flexibility to potentially increase its prices during a disruption impacts its decisions on the level of reserve inventory or reserve capacity to carry in anticipation of disruptions. While the reserve inventory provides a certain quantity of inventory that the firm can continue to sell during a disruption, reserve capacity allows the firm to maintain production during a disruption at a certain production rate. Specifically, we consider a firm producing a single product and that is exposed to random disruptions. The firm first decides on the level of reserve inventory or reserve capacity to carry in anticipation of disruptions. When a disruption does occur, it may then choose to adjust its price to better align demand with the supply restrictions during the disruption. We characterize the firm's optimal pricing decisions during disruptions, and the level of reserve inventory or reserve capacity to hold in anticipation of disruptions. We find that a certain level of pricing flexibility may be required to justify holding reserve inventory or reserve capacity. Further, we also show that while a firm's pricing flexibility during a disruption and reserve capacity decisions are substitutes, pricing flexibility and reserve inventory may act either as substitutes or complements, that is, a firm may be incentivized

to carry a lower or higher amount of reserve inventory if it possesses further flexibility to increase its prices during a disruption.

4 - Giving Deep Attention to Consumer Preferences with Large Language Models

Joshua Foster, Fredrik Odegaard

We use the natural language descriptions of exotic and collectible vehicles from online auction markets to semi-nonparametrically estimate the primitives of demand (private valuations, number of potential bidders) for each individual vehicle in our dataset. The first stage of our estimation method fine-tunes a large language model (RoBERTa, Liu et al., 2019) to predict the inputs of our demand estimators using the descriptions provided for each vehicle. We then append a multi-layer perceptron to the tuned language model that projects into the parameter space of these estimators so that a second stage training can recover the primitives of interest. Our identification method relies on the structural features of specific bids submitted in these markets, which can proxy for valuations under our data generation assumptions. Finally, we demonstrate how this model can generate counterfactual analyses using new natural language descriptions within the defined product space.

1 - A Black Widow Optimization for The Time-dependent Vehicle Routing Problem with Fleet and Crew Assignment

Antonia Ilabaca, Germán Paredes-Belmar

This paper focuses on the efficient distribution of goods in urban areas by using the time-dependent vehicle routing problem with fleet and crew assignment (TD-VRPFCA). The objective is to find the best routes for a group of vehicles to deliver goods to a set of destinations, considering various factors that are specific to city logistics, such as traffic congestion, the locations of different buildings, and the difficulties that delivery workers may face in accessing these places. Unlike the traditional vehicle routing problem, our focus is on the efficient crew assignment for delivery vehicles. The crew composition can consist of different roles, such as drivers, delivery workers, or a multifunctional worker who perform both driving and delivery tasks. The crew assignment aims to minimize the total distribution time, considering that service and travel time depend on the time of day and the location of each vehicle due to the traffic flow of people in the buildings and congestion on the streets.

To solve this problem, we propose a new algorithm called Black Widow Optimization (BWO) for Vehicle Routing Problems. BWO is an efficient metaheuristic algorithm proposed for continuous variables, but in this paper, we propose an algorithm for mixed integer variables. The resulting set of efficient routes and crew vehicle assignments can support decision-making and improve customer service.

2 - A Multi-Trip Periodic Vehicle Routing Problem with Time Windows, Split Delivery for Simultaneous Pick-Up and Delivery

Gorkem Yilmaz

Efficient vehicle routing and delivery planning are critical challenges in logistics systems, impacting operational effectiveness and cost efficiency. Planners are tasked with devising effective delivery and pick-up schedules to meet customers' needs, considering factors such as pick-up and demand quantities per customer, available working hours, shift times, total distances between customer locations, cost parameters, and various transportation constraints. Delivery planners allocate

vehicles, determine the start time of service, optimize vehicle routes within specified time windows, schedule shifts, and decide on the number of tours for each vehicle. These actions aim to maximize vehicle utilization and meet requirements at minimum cost. We propose mixed integer programming models that reduce the logistic costs and number of vehicle traffic by combining shipments from different customers. To solve large problems, we propose a decomposition-based heuristics that separates periods by considering time windows and setting an objective that first minimizes the number of used vehicles in each period. The results show that inefficient transportation between two nodes is avoided, the numbers of vehicles are decreased, the utilization rate of each vehicle is increased, and vehicle traffic is reduced in each customer area.

3 - A Local Search metaheuristic for the last-mile Vehicle Routing Problem with Delivery Options

Eleftherios Manousakis, Ioannis Kitsos Kalyvianakis, Angelos Omirolis, Emmanouil Zachariadis

The Vehicle Routing Problem with Delivery Options (VRPDO) extends the classical Vehicle Routing Problem (VRP) by incorporating multiple alternative delivery locations per customer with potentially distinct time windows, ordered according to customer preferences. These alternative destinations, such as homes, workplaces, or lockers, introduce additional complexities, including varying capacity and time window constraints at shared delivery points. Ensuring customer satisfaction involves adhering to minimal service level requirements, reflecting preferences for alternative delivery locations. The VRPDO calls for determining optimal routes and delivery locations while minimizing total routing costs and satisfying all time window, capacity and service level constraints. We propose a minimum insertion heuristic for generating initial solutions, followed by a local search framework to refine these solutions. The framework incorporates traditional routing operators alongside a novel service level-related operator capable of adjusting delivery locations to satisfy customer preferences. Initial findings demonstrate the effectiveness of our approach in achieving high solution quality while maintaining computational efficiency.

4 - The Two-Echelon Inventory-Routing Problem: A Matheuristic Approach

Sara Charaf, Duygu Tas, Simme Douwe Flapper, Tom van Woensel

The two-echelon inventory-routing problem (2E-IRP) addresses the coordination of vehicle routing and inventory management throughout a two-echelon supply network. The latter consists of intermediate facilities that are located in the city outskirts, supplied from distant depots, and serve a set of geographically widespread customers. The customers' demand is met from either their local inventory or intermediate facilities' inventory. The aim is to minimize the transportation and inventory costs while meeting customers' demands over a finite discrete planning horizon. We introduce an effective tabu search-based matheuristic approach to solve it. Computational experiments show that our approach achieves good results regarding solution quality and computational time. For small instances, the matheuristic finds 99 optimal solutions out of 165 known optimal solutions and achieves an average gap of (-2.32%) over 235 instances with a known best upper bound only. Our approach also solves larger instances within a reasonable computational time and provides upper bounds for all 400 large-sized instances for the first time to the literature.

1 - Exact solution approaches for the nested p-center problem

Christof Brandstetter, Markus Sinnl

Consistent solutions are vital in multi-period facility location problems, especially for long-term planning. In this work, we present various exact solution approaches on the nested p-center problem, a recently introduced variation of the well-known (vertex) p-center problem, which can be defined as follows: Given a set of locations and a finite time horizon, in each time period, a set of open facilities needs to be opened, where the set of a time period, needs to be a subset of the set of open facilities in the following period. The goal is to minimize the sum of the maximal distance between any customer and its nearest open facility over the time horizon.

In our work, we present different mixed integer linear programming formulations on the nested p-center problem, which are solved using exact solution methods like Bender's Decomposition or branch-and-bound. Furthermore, we have developed a solution framework to increase the performance in terms of runtime on all formulations by adopting a diverse set of methods, like cut separation, lifted optimality cuts or preprocessing.

The different formulations and methods used are analyzed in a computational study on benchmark instances, known from previous literature and the managerial implications of the nesting property are analyzed.

2 - Variable aggregation in a Benders decomposition for the p-median problem

Rick Willemsen, Daniel Aloise, Raf Jans

The p-median problem is a classical discrete location problem and is equivalent to the well-known k-medoids problem in the unsupervised clustering literature. The aim is to select p centers while minimizing the sum of distances from each customer to its nearest center. Recent advancements in solving the p-median and related problems have successfully leveraged Benders decomposition methods. In order to reduce the number of variables and possibly the number of Benders cuts in these models, it is possible to aggregate distance variables corresponding to customers. We propose to partially aggregate the distance variables based on an initial solution: aggregation occurs only when the corresponding customers are assigned to the same center in the initial solution. In addition, we propose a set of tailored valid inequalities for these aggregated variables. Initial experiments indicate that our model, post-initialization, provides a stronger lower bound, thereby accelerating the resolution of the root node. Furthermore, this approach seems to positively impact the branching procedure, leading to an overall faster Benders decomposition method.

3 - Capacitated service location when fairness principles are significant

Inigo Martín Melero, Mercedes Landete, Juan Carlos Gonçalves-Dosantos, Joaquín Sánchez-Soriano

In this work we address the problem of deciding where to install service points when it is certain that the total demand is greater than the capacity that the installed system can achieve. The starting point is a set of potential locations for service points and a set of locations where customers with known demands are. There is a budget to install p service centers with different capacities, although the sum of these capacities is less than the sum of the demands. The problem is deciding where to install these p centers using allocation criteria from conflicting claims problems. Equal losses, equal awards or proportional allocation approaches are considered. All the optimization models we introduce are mixed linear, their optimal solutions illustrate the effect of scarce resource management on the service centers location. Likewise, in addition to including different fairness criteria in the objective function of the optimization models, we also analyze different families of constraints that allow us to guarantee other desirable properties such as that two customers with the same demand have similar services. We check the conditions under which the solutions of our models are efficient in the sense that all capacity is allocated. Finally, we illustrate the behavior of the optimization models by solving instances of different sizes.

4 - Facility location under agglomeration and two-stage customers' spatial choice

Vladimir Marianov, Gonzalo Mendez-Vogel, Armin Lüer-Villagra, H.a. Eisel

Most stores offering clothing, electronics, phones, and similar shopping goods, agglomerate in clusters —malls or shopping districts. This location pattern facilitates multipurpose shopping, which consists of purchasing more than one good during the same trip, and comparison shopping, the process of comparing products of different stores, but serving the same purpose, before purchasing. Clustering leads to a two-stage (or sequential) destination choice by customers. They decide first on a cluster to visit, and then, the stores to visit within the cluster. The two stages are not independent, as the first decision depends on the stores in the cluster: if a consumer is in search of a product serving a purpose, the number of alternative stores that fulfill that purpose in the cluster, and the number of stores offering other products in the same cluster, affect the selection of the chosen cluster. This agglomeration and the correlation are not represented in the customer choice rules common in location models (Multinomial Logit, Gravitational rules), as they do not take into account the spatial distribution of stores, although modifications to gravitational and Logit rules have been suggested by marketing researchers. We explore a Nested Logit model fit for the spatial choice process and later use it to formulate, for the first time, a location model that includes the two-stage process and the spatial agglomeration. Preliminary computational experience is also presented.

1 - Optimizing RoRo Stevedoring Operations: Dual Cycling for Vessel Turnaround Efficiency

Teresa Marquardt, Arne Heinold, Catherine Cleophas, Frank Meisel

This work addresses the challenge of decreasing vessel turnaround time in Roll-on Roll-off (RoRo) shipping as a means to achieve emission reduction by enabling time savings that allow for slower sailing. RoRo shipping has received comparatively less attention than container shipping by research, yet it is of high relevance, especially in Europe with its long shorelines. The study investigates the potential of stevedoring optimization by extending the Dual Cycling Problem from the literature, where on- and off-loading operations happen simultaneously. To that end, we model a continuous time horizon, differentiate between driver-handled cargo and stevedore-handled cargo with heterogeneous processing times, and solve the assignment and sequencing of operations for the stevedores. We propose a mixed integer linear programming model to solve the resulting problem. Given high computational effort for instances of realistic size, we further propose a biased random-key genetic algorithm, a random construction heuristic, and rule-based heuristics to find good solutions in short runtime. We present computational results demonstrating the effectiveness of the proposed approaches under varying conditions. Additionally, managerial insights clarify the superiority of stevedoring with a dual cycling strategy over single cycling, the impact of different cargo-handling policies, and the effects of different stowage policies on the turnaround time.

2 - Comparison of 3 modelling approaches for stowage of heterogeneous cargo on RoRo ships with stability requirements

Oliver Rise Thomsen, Magnus Vilhelm Barrett Levinsen, Alastair Main, Line Reinhardt, Dario Pacino

This study evaluates the three main representations methods of the RoRo stowage planning problem for heterogeneous cargo and stability constraints. The lane, grid and hybrid-slot model are formulated and implemented in an equal manner to compare them. All formulations accounts for vessel stability by ensuring that the vertical centers of gravity, shear force and bending moment are within their respective limits. The results show the hybrid-slot approach create the best solutions on all instances across test on a small, medium and large ship.

3 - A rolling horizon approach to a two-stage stochastic model for dual cycling under uncertainty in RoRo terminals

Line Reinhardt, Asefe Forghani, Dario Pacino

Dual cycling, which executes loading and unloading simultaneously, is acknowledged for reducing handling time at the port, thus enabling slow steaming and GHG reduction. Previous studies on dual cycling mainly focused on container shipping with deterministic cargo arrivals, which are unsuitable for the RoRo (Roll-on/Roll-off) sector's inherent uncertainties. Our research bridges this gap by proposing a two-stage stochastic model that aims to minimise the total discharging and loading operation time under uncertain cargo arrivals. The model is based on several assumptions: cargo is distinguished as unaccompanied trailers and classified by weight, and it is assumed that the ship's space is divided into slots for distinct cargo types based on a predetermined weight-based plan; cargo arrivals follow a stochastic pattern, and the ship should wait until all planned cargoes have arrived and are loaded. Loading and unloading follow specific precedence rules reflecting the deck layout and safety requirements, and the number of tugs during the entire operations remains constant. Addressing the computational challenge, we propose a heuristic rolling horizon approach and a scenario reduction framework. As a case study, the proposed model was implemented on a shuttle vessel's tank deck. The results demonstrated that, compared to the classical discharge-then-load policy, dual cycling achieved an 11.11% turnaround time reduction and a 38% tug utilisation improvement.

4 - Scheduling and conflict-free routing of automated guided vehicles in container terminals

Mohamed Ben Ahmed, Steffen Bakker, Kjetil Fagerholt

In automated container terminals, automated guided vehicles (AGVs) are used to transport containers from the quayside to their location in the storage area. AGVs navigate between key terminal locations, following predefined guide paths. They have bidirectional movement capabilities that enable forward and backward travel, and their movements remain predominantly linear, aligning with the terminal's layout. Limited buffer space at pickup and drop-off points causes AGVs to wait until ongoing operations conclude, creating delays. Delays may also occur when a quay crane must wait for an AGV. Therefore, minimizing both the delay times of QCs and the travel time of AGVs is vital for reducing vessel dwell time and enhancing operational efficiency. AGV conflicts, like deadlocks and collisions, worsen delays, causing congestion and decreased throughput. Implementing advanced routing algorithms and control systems is thereby essential to optimize AGV movements and enhance operational efficiency. This work presents a time-space network formulation for the problem scheduling and routing of AGVs in container terminals where conflict avoidance constraints are explicitly modeled. The problem's objective is to minimize the vessel's dwell time while ensuring the smooth flow of container handling operations. A solution method that combines a mathematical formulation and an insertion heuristic is implemented. Testing and validation are conducted using real data from Norwegian port cases.

Tools for Risk Management

*Invited session*Chair: Francesco Biancalani**1 - Effect of the Inflation Reduction Act on Equity Raised Values in the US Healthcare Macro-Sector: A Matrix-Completion Approach***Francesco Biancalani, Giorgio Gneco, Andrea Signori, Silvio Vismara*

We investigate the effect of the recent Inflation Reduction Act (IRA) - introduced in August 2022 - on equity raised in the US healthcare macro-sector. For the data analysis, we employ a panel approach, in which a subset of entries of a matrix of new equity raised values is observed, and one aims to predict counterfactual values for the missing entries (i.e., the equity raised values in the US healthcare macro-sector that would have been obtained after August 2022, in the absence of the IRA). Rows of the data matrix refer to specific pairs having the form region/macro-sector (for a total of $3 \times 5 = 15$ rows), and their columns to specific quarters of the year (for a total of $2 \times 4 = 8$ quarters, 4 before the adoption of the policy, and 4 after that event). Such predictions are obtained by employing a supervised machine-learning method named matrix completion, whose use for causal panel data analysis has been recently advocated in a celebrated work by Athey et al. in 2021. According to the results of our analysis, the effect of the IRA was to increase equity raised values in the US healthcare macro-sector during the treatment period, as compared to their predicted counterfactual values.

2 - Impact of Sentiment analysis on Energy Sector Stock Prices : A FinBERT Approach*Rania Hentati Kaffel, Sarra Ben Yahia, José Ángel García Sánchez*

This paper provides accurate estimations of the impact of sentiment analysis on forecasting trends in stock prices. We use FinBERT, a pre-trained and fine-tuned NLP model to label and to score a large web-scraped data (tweets posts and Reddit discussions) of 10 selected energy stock daily returns and the S&P Energy Index spanning from 2018 to 2023. Our approach confirms: i) the accuracy of stock price predictions going up to 85%. ii) Results are highly sensitive to the test period and confirm the link between risk aversion and negatif or positif score. Also, a novel contribution is provided and consist on employing time series model to capture the temporal dependencies and autocorrelation structures within both the sentiment scores and stock returns data. Our study reinforces the concept of market efficiency and offers empirical evidence regarding the delayed influence of emotional states on stock returns.

3 - Copula-based synthetic networks generation*Giulia Rotundo, Roy Cerqueti*

In this work, we elaborate on the concept of assortative mixing. The role of assortativity contagions has been widely studied: in the spread of epidemics, in systemic risk, and in the resilience of networks, just to point out a few. The classic definition of assortativity through the Pearson correlation coefficient among the degrees of the nodes at the end of each edge captures the linear dependencies among the degrees of the connected nodes. We are going to push forward the concept of assortative mixing allowing for non linear dependencies. In order to achieve this task, we fix the marginal distributions as the most detected from the empirical data sets and we base on the generation of complex networks through copulas. The approach is different from the classic configuration model and its extensions which allow to build a network with a target level of correlation. It is worth mentioning that the application of the technique goes beyond the mere result of simulating networks. Actually, the possibility to generate networks with specific properties allows to have a null model for investigating the role of topological structures in specific problems. For instance, the generation of synthetic data keeping the statistical distribution of real data sets is currently successfully used in machine learning to enlarge the training set.

4 - An analytical study of variable annuities with surrender option*Gabriele Stabile, Alessandro Milazzo, Tiziano De Angelis*

Variable annuities (VAs) are insurance contracts designed to meet retirement and long-term investment goals. These products combine the participation in equity performance with insurance coverages. The subscriber of a VA (policyholder) enters the contract by paying a premium, and chooses to invest it from a selection of investment funds. Besides the life insurance protection, VAs provide a number of financial guarantees and options. A minimum rate is guaranteed by the insurer in order to protect the policyholder's capital against market downturns. Moreover, the policyholder has the right to early terminate the contract (surrender option) and to receive the account value. In general, a penalty is applied by the insurer in case of early surrender, which decreases in time. These financial guarantees are financed by a fee paid by the policyholder, typically in the form of a fixed proportion of the account value. At maturity, the policyholder can choose to obtain the account value or convert it into an annuity stream. These features of the VAs contracts are liabilities to the issuer and constitute a potential hazard to company solvency. In this paper we provide an analytical study of the pricing formula for the VAs and a characterisation of the optimal exercise strategy for the surrender option.

Routing in Warehouses

Stream: VeRoLog - Vehicle Routing and Logistics

*Invited session*Chair: Felix Weidinger**1 - Integrating Order Picking and Delivery Decisions in a Dynamic Setting***Ruben D'Haen, Katrien Ramaekers, Claudia Archetti, Kris Braekers*

The growing importance of e-commerce retail, accompanied with the need of offering a high customer service level, requires companies to optimise their operations. One possible area of improvement is the integration of order picking and delivery decisions. If a new customer order arrives, the requested items first need to be picked in the warehouse. Afterwards, the items are delivered to the customer's location. Traditionally, the picking and delivery operations are considered individually and in a sequential manner. By using integrated decision making, however, more efficient operations can be obtained.

Since customers demand very fast deliveries, the use of an online optimisation strategy is preferred, as it allows to consider new customer orders very quickly in the current operating schedule. While previous research considered the integration of picking and delivery in a static problem setting, its impact in a dynamic setting is yet unstudied.

We propose new metaheuristic algorithms to solve the integrated picking and delivery problem in a dynamic setting. The performance of several algorithms, i.e., a simple sequential algorithm, an iterative algorithm and two integrated algorithms, is compared to show the benefits of using a more involved optimisation strategy.

2 - Synchronizing Human-Robot Cooperation in Warehouses: Integrated Order Batching and Routing Problem in AMR-Assisted Picking Systems*Sina Khodaei, Melih Celik, Vaggelis Giannikas*

With technological advancements and the growth of e-commerce industries, warehouses are taking advantage of robots' assistance to gain more productivity. This increasing usage, however, has directed them to face more challenges in terms of human-robot collaboration, specifically in the order-picking process. In this study, we address the problem of human-robot coordination in a picker-to-part picking system,

where automated mobile robots (AMRs) that are equipped with bins move through the warehouse to collect the items on the batch lists. Human pickers, on the other hand, travel between item locations to load the AMRs. As there are fewer human pickers than AMRs, efficient routing of both human and robot pickers plays a pivotal role in determining the productivity of the system. Hence, the main decisions of the problem are the batching of orders for the AMRs and the routes of all pickers. To address this problem, we propose a mathematical formulation and a novel two-stage decomposition-based heuristic approach to minimise the makespan. The first stage of our heuristic solves the integrated batching-routing problem for the AMRs using a variable neighbourhood search approach, and then, in the second stage, by setting AMRs' arrival times at each location as due dates for the human pickers, the algorithm searches for their routes. We also test the performance of the heuristic and generate managerial insights using randomly generated instances on different warehouse structures.

3 - Multi-Depot Dynamic Routing of Multiple Pickers With Order Priorities and Due Dates in Smart Warehouses

Xiaochen Feng, Arsham Atashi Khoei, Melih Celik, Vaggelis Giannikas, Niccolò Corsini

The fast development of e-commerce and higher customer expectations for quicker order delivery emphasise the importance of efficient management in urban warehouses, which operate in a setting with dynamic order patterns and stringent order lead time. Dynamic order-picking strategies became increasingly important as they allow for the dynamic assigning of incoming orders to pickers during each pick cycle. Collaborating with an industrial partner that develops cutting-edge Internet-of-Things technologies and platforms for smart warehousing, our proposed model extends the original dynamic order-picking problem by considering the due date and the order priority. Given the set of pickers and the sets of continuously coming new orders, our model focuses on assigning incoming orders to pickers and redesigning the routes of each picker on the sequence of item locations they will visit and the depot they will return to while meeting the time frame requirements for each order and considering the order priority in order to ensure a more efficient order-picking process in smart warehouses. Due to the time constraints and the need for quick response to the complex order fulfilment processes, the efficiency of the algorithm is as important as the solution quality. We propose a problem-tailored heuristic solution approach by extending the well-known heuristics, which can efficiently deal with the decisions of picklist updating, picker assignment, and rerouting.

4 - A Flexible Procedure for the Single Picker Routing Problem With Scattered Storage

Felix Weidinger, Constantin Wildt

E-commerce retailers have substantially reinvented warehousing. To pick small, heterogeneous orders in a short period of time, novel warehousing approaches have been developed. The equivalent of classical manual warehousing is, hereby, mixed-shelf storage; where pieces of the same SKU can be found at many storage positions. This, however, makes the picker routing problem, which aims to find a shortest picking tour for collecting all items on the current pick-list, a combined selection and sequencing problem. The storage positions to be visited must be selected, and a tour through the selected positions must be planned. The resulting problem, often referred to as the Single Picker Routing Problem with Scattered Storage (SPRP-SS), has gained much attention recently. Most of the proposed procedures, however, assume a rectangular layout of warehouses, such that the subproblem, once the positions to be visited are selected, is solvable in polynomial time. However, for warehouses in existing dense inner-city buildings or multi-level mezzanine systems, the property of rectangular layouts is not met. In the talk, an exact and heuristic solution approach for solving the SPRP-SS for arbitrary distance matrices is presented and discussed.

Immanuel Bomze

In some ML communities, researchers claim that obtaining local solutions of optimality criteria is often sufficient to provide a meaningful and accurate data model in real-world analytics. However, this is simply incorrect and sometimes dangerously misleading, particularly when it comes to highly structured problems involving non-convexity such as discrete decisions (binary variables). This talk will advocate the necessity of research efforts in the quest for global solutions and strong rigorous bounds for quality guarantees, showcased on one of the nowadays most popular domains – cardinality-constrained models. These models try to achieve fairness, transparency and explainability in AI applications, ranging from Math.Finance/Economics to social and life sciences.

From a computational viewpoint, it may be tempting to replace the zero-norm (number of nonzero variables) with surrogates, for the benefit of tractability. We argue that these relaxations come too early. Instead, we propose to incorporate the true zero-norm into the base model and treat this either by MILP relaxations or else by lifting to tractable conic optimization models. Both in practice and in theory, these have proved to achieve much stronger bounds than the usual LP-based ones, and therefore they may, more reliably and based upon exact arguments, assess the quality of proposals coming from other techniques in a more precise way. With some effort invested in the theory (aka later relaxations), the resulting models are still scalable and would guarantee computational performance closer to reality and/or optimality.

1 - Advanced Demand-Capacity Balancing Mechanisms to Improve Performance of European Air Traffic Networks

Jan-Rasmus Kuennen

Air travel disruptions due to Covid recovery, strikes, and military presence highlight the need for efficient airspace management. The dissertation presents demand-capacity balancing mechanisms aimed at improving European air traffic management (ATM) performance. The first paper introduces dynamically priced flexible trajectory products to manage demand, based on an optimizing routing under capacity constraints. The second paper proposes a simulation-optimization approach for cross-border capacity planning, showing potential for significant delay reductions. Finally, the third paper analyzes measures to reduce aviation emissions through capacity planning and pricing initiatives. Impacting both research and practice, the findings offer innovative solutions for managing demand-capacity imbalances post-Covid, potentially reshaping European airspace management.

2 - Adjustable Robust Optimization with Non-Linear Recourse

Henri Lefebvre

Over the last century, mathematical optimization has become a prominent tool for decision making. Its systematic application in practical fields such as economics, logistics or defense led to the development of algorithmic methods with ever increasing efficiency. Indeed, for a variety of real-world problems, finding an optimal decision among a set of (implicitly or explicitly) predefined alternatives has become conceivable in reasonable time. In the last decades, however, the research community raised more and more attention to the role of uncertainty in the optimization process. In particular, one may question the notion of optimality, and even feasibility, when studying decision problems with unknown or imprecise input parameters.

In this talk, we study a class of optimization problems which suffer from imprecise input data and feature a two-stage decision process, i.e., where decisions are made in a sequential order and where unknown parameters are revealed throughout the stages. The applications of such problems are plethora in practical fields such as, e.g., facility location problems with uncertain demands, transportation problems with uncertain costs or scheduling under uncertain processing times. The uncertainty is dealt with a robust optimization (RO) viewpoint (also known as "worst-case perspective") and we present original contributions to the RO literature on both the theoretical and practical side.

Chair: Grzegorz Pawlak

1 - Multi-objective optimal recommender systems

Elaheh Lotfian, Alireza Kabgani

In this talk, we introduce a multi-objective recommender system aimed at enhancing both the accuracy and diversity of top-n recommendation lists. To address this optimization challenge, we present a customized hybrid AMOSA_NSGA-II (HAN) algorithm, facilitating the creation of a Pareto set for top-n lists. Additionally, we provide a methodology for selecting the optimal list for each user within this Pareto set. Initially, we generate preliminary top-n lists through item-based collaborative filtering. Subsequently, the second stage addresses a bi-objective optimization problem related to recommendation lists, utilizing the customized HAN algorithm. Finally, the third stage focuses on producing optimal personalized top-n lists for individual users. To assess the effectiveness of our method, we implement it on real-world datasets, conduct a thorough performance evaluation, and compare its results with existing approaches in the literature.

2 - Bidding in Online Display Advertising: A Deep Reinforcement Learning Model for Mobile Gaming Market

Qirui Yang, Frank Chen, Mengzhuo Guo, Houmin Yan, Qingpeng Zhang

When a user opens a website or app, there are often several advertisements interspersed. Generally, whenever an advertisement appears, loads, and is seen on a user's screen, it is referred to as an impression. For advertisers, an impression signifies an opportunity for their ads to be viewed. Therefore, real-time bidding (RTB) has emerged as a prominent paradigm, allowing advertisers to procure impressions through instantaneous automatic auctions. In RTB, the goal for advertisers is to maximize the total revenue generated from the impressions they win while considering constraints such as budget. Due to the difficulty in estimating the value of impressions and the bids of competitors, determining the optimal bid for each impression becomes a

challenging problem for advertisers. In our work, we first propose a novel definition of impression value under the background of the mobile gaming market, which takes into account players' in-game purchase, conversion revenue, and publisher characteristics. In addition, to enhance the interpretability of the strategy, we introduce a two-part method: the first part employs reinforcement learning techniques to obtain a two-dimensional vector based on an optimization problem, and the second part utilizes this vector to guide modifications to existing generic bidding paradigms in the industry. Real-world experiments demonstrate an increase in return on investment by over 80% compared to current practices after applying our method.

3 - An Algorithmic Approach to Managing Supply Chain Data Security: The Differentially Private Newsvendor

Du Chen, Geoffrey A. Chua

Data is now unanimously considered a key firm asset for enabling better operational decisions. However, data-driven decisions can inadvertently expose private data, leaving firms vulnerable to unforeseen danger. How to manage data security risks by protecting data from being inferred from observable decisions thus becomes an important question. In this paper, we focus on data security in supply chains due to their data-intensive nature. Specifically, we examine a data-driven contextual newsvendor problem. To quantify and ensure data security, we adopt the notion of differential privacy, a mathematically rigorous measure of data security that limits an attacker's inference accuracy. Employing convolution smoothing and noise injection, we propose several differentially private algorithms that provably guarantee both data security and asymptotic optimality with (near) optimal rates. In the non-asymptotic regime, we further identify three drivers of the cost of data security; namely, dataset size, context, and number of products. This finding suggests that gathering more data, collecting detailed context, and pooling data from multiple products can lower data security cost. Lastly, we examine the impact of a newsvendor's private algorithms on supply chain partners. We discover additional distortion to the demand signaling process and lower profit share for an upstream supplier.

4 - Applying Mathematical Programming to Visualize Text Summarization from Multiple Perspectives

Li-Ching Ma

The widespread adoption of the Internet and social networks has resulted in an explosion of data from diverse sources, often causing information overload. Consequently, a growing need for text summarization has emerged to assist users in quickly digesting information. Additionally, many practical scenarios require comparative opinions from multiple perspectives. However, most research tends to address issues from a single viewpoint. The aim of this study is to propose a graphical text summarization approach that integrates multiple perspectives through the utilization of text mining and goal-programming optimization methods. From the idea of a data warehouse schema, this study constructs three-layer heterogeneous graphs to represent entities, nouns, adjectives, and their interrelationships. Star and Snowflake diagrams are constructed to show relationships between nouns and adjectives. Additionally, a constellation diagram is introduced to visualize the relationships among different entities. The proposed approach offers several significant advantages. It provides a straightforward and easily understandable method to summarize a large amount of text content on a single graph. Users can, therefore, significantly reduce the time spent individually browsing numerous documents or reviews. Decision-makers can compare the strengths and weaknesses of different entities from an integrated graph or understand the differences in user opinions from various perspectives.

1 - A Novel Ensemble Framework for XAI-Based Feature Selection in Machine Learning Models

Sureyya Ozogur-Akyuz, Halil Ibrahim Demirel

This study introduces an innovative ensemble framework that leverages Explainable Artificial Intelligence (XAI) to enhance feature selection processes in machine learning (ML) models. The primary aim is to improve the interpretability and predictive performance of these models. Our approach integrates multiple ensemble learning algorithms, including Gradient Boosting Machines and Random Forests, with XAI techniques like SHAP to create a transparent, interpretable model. We evaluate our framework on various datasets, demonstrating its ability to maintain high predictive accuracy while providing insights into the feature selection process. The results indicate that our ensemble framework significantly enhances model transparency and interpretability without compromising on performance.

2 - Learning a Policy for the Real-Time Inventory Rack Storage Assignment and Replenishment Problem

Sander Teck, San Tu Pham, Louis-Martin Rousseau, Pieter Vansteenwegen

The e-commerce sector is rapidly automating warehouse operations, necessitating efficient control systems to manage this growing complexity. This study investigates Robotic Mobile Fulfillment Systems (RMFS), employing autonomous mobile robots (AMRs) for inventory rack management. These systems eliminate the need for human operators within the storage area, with AMRs responsible for both storing and retrieving movable inventory racks. Human operators stationed at workstations alongside the storage area fulfill customer orders by picking goods from these racks. RMFS dynamically adjusts rack positions based on usage frequency. Furthermore, effective restocking timing is crucial to prevent operation delays. Real-time scheduling, especially in inventory rack storage and replenishment, is essential for optimal performance.

To minimize cycle time, a deep reinforcement learning (DRL) approach is proposed. The storage area is divided into zones to facilitate efficient decision-making. The learning agent interacts with the environment, observes changes in its state, and learns through trial-and-error from these interactions. Thereby, it is able to construct a policy by mapping environment states to actions. Experimental results demonstrate significant cycle time improvements compared to traditional decision rules. The study underscores the importance of real-time decision-making for the storage assignment and replenishment problem.

3 - The optimal input-independent baseline for binary classification

Sandjai Bhulai, Joris Pries, Etienne van de Bijl, Jan Klein, Rob van der Mei

Before any binary classification model is taken into practice, it is important to validate its performance on a proper test set. Without a frame of reference given by a baseline method, it is impossible to determine if a score is "good" or "bad." The goal of this paper is to examine all baseline methods that are independent of feature values and determine which model is the "best" and why. By identifying which baseline models are optimal, a crucial selection decision in the evaluation process is simplified. We prove that the recently proposed Dutch Draw baseline is the best input-independent classifier (independent of feature values) for all order-invariant measures (independent of sequence

order) assuming that the samples are randomly shuffled. This means that the Dutch Draw baseline is the optimal baseline under these intuitive requirements and should therefore be used in practice.

Cutting and Packing 2 - 2D irregular

Stream: Cutting and Packing (ESICUP)
Invited session

Chair: José Fernando Oliveira

1 - A heuristic for packing weighted unequal circles in circular containers

Yun Yang, Somayeh Allahyari, Gu Pang, Yong Lin

The Weighted Circles Packing Problem (WCPP) is an extension of the classical circle packing problem with practical applications across various industries, including logistics, facility layout, automotive, manufacturing, telecommunications, and materials science. In WCPP, each circle is characterized not only by its size (i.e., radius) but also by a weight value, representing cost, value, priority, or other relevant metrics. This introduces complexity to the problem, as algorithms need to simultaneously consider the physical arrangement of circles and optimize their total weighted configuration. This study aims to maximize both the number of unequally sized circles packed in a container and the total layout score of the packed weighted circles while adhering to the constraint of non-overlapping circles or between each circle and the container. For this problem, we develop an Iterated Local Search meta-heuristic algorithm where the initial feasible solution generated using polar coordinates and geometric methods is improved iteratively by local search and shaking procedures. Computational tests on a relaxed version of this problem using the benchmark published in López and Beasley (EJOR, 2016) clearly indicate the effectiveness and significant time-efficiency of the develop

2 - Decoupling Geometry from Optimization in 2D irregular Cutting and Packing problems: an Open-Source Collision Detection Engine

Jeroen Gardeyn, Greet Vanden Berghe, Tony Wauters

While the objectives and particulars of irregular C&P problems can differ, they all share a common feasibility check: whether or not an item can be placed at a certain position. This check is particularly complex due to the geometric irregularity of the items and containers. For C&P problems, there is currently no sufficiently general approach to tackle this task in an easy and efficient manner. This not only heightens the barrier to entry, but also results in researchers having to continuously reinvent the wheel whenever they are addressing new problems or developing new approaches for existing problems. This work aims to decouple geometry from optimization and develop a high-performing adaptable engine, capable of efficiently handling the geometric component of irregular C&P problems. We envisage two target audiences. First, there are those who simply want to focus on their optimization problem at hand and who would therefore greatly benefit from having an engine they can incorporate into their own methodology. Such an engine would essentially outsource the geometric challenge and enable them to focus their efforts on developing smart solution methods. The second target audience are those who, rather than solving problems themselves, might have good ideas concerning how to further improve and refine this open-source engine. The project is called "jagua-rs" and is publicly available at: <https://github.com/JeroenGar/jagua-rs>

3 - Extreme Points-Based Heuristic for Irregular Panel 2D-Bin Packing with Defects

Elsa Silva, Tiago Silveira, Maria Antónia Carravilla, José Fernando Oliveira, Matheus Campinho

The 2-dimensional Bin Packing Problem addressed in this presentation arises within the ornamental stone industry, where heavy stone panels of irregular shapes, often with defects, must be cut to meet the demand for rectangular items. The cutting process in this industry is subject to practical constraints, primarily influenced by the thickness of the stone panels and the cutting technology employed, resulting in an effect known as overcut. Overcutting involves cutting the raw material beyond the edge of the intended piece. This effect can damage pieces placed on top of the cut unless there is sufficient separation between the pieces or alignment with another cut in the same direction.

To the best of our knowledge, this constraint has never been explicitly addressed in the literature, making it a non-trivial challenge to overcome.

In response to these challenges, a novel approach is proposed. An extreme point-based heuristic has been developed to solve the problem, enhanced by a local search procedure based on the two-exchange heuristic. The irregularity of the panels is managed through a transformation process that converts irregular shapes into regular ones, simplifying the structure. Computational experiments using real-world data have been conducted to validate the effectiveness of the proposed approach, and the results and practical applications are thoroughly discussed.

1 - Green Bonds and Environmental Scores: analysing impact and factors of environmental performance

Christina Erlwein-Sayer

Green bonds are widely utilized financial instruments designed for the purpose of funding environmentally friendly projects. Positive environmental effects of green bonds have been analyzed previously. These investigations largely rely on the Difference-in-difference models to gauge the overall impacts. We investigate the influence of corporate green bonds on the environmental performance of issuers at an individual level and employ a Controlled Interrupted Time Series Model. When statistically significant effects on the issuers' environmental performance, measured by the E score of the issuers' ESG, are determined, two sequential experiments are performed: firstly, we probe into the factors that can influence the issuance of green bonds. Secondly, we examine the interrelations between company characteristics, issuer characteristics, and the magnitude of the effects released by green bonds. To address the first and second experiment, we build a random forest and a generalized additive model, respectively. Our findings indicate that the environmental performance of most issuers improves following the issuance of green bonds. While both bond and company characteristics influence the impact of green bonds, it is the company's characteristics that play a more pivotal role.

2 - Day-ahead probability forecasting for redispatch 2.0 measures

Vlad Bolovaneanu

The purpose is to advance a data-driven, day-ahead forecasting model for assessing the probability, direction, and scale (load) of electrical congestions within Germany's complex electrical power grid. Utilizing state-of-the-art machine learning algorithms, the model is specifically designed to operate on an hourly basis, thereby offering timely insights for grid management. The analysis uncovers compelling evidence that key exogenous variables, such as real-time meteorological conditions, electricity supply-demand indicators, and Brent oil price fluctuations,

can be harnessed to make highly reliable predictions concerning grid congestion events. Also, seasonal patterns are uncovered. Our contribution has the potential to serve as a useful resource for transmission system operators (TSOs) and policymakers interested in grid management and cost mitigation efforts.

3 - Spillovers between risk indices and the cryptocurrency market

Barbara Będowska-Sójka, Joanna Górka

The aim of the paper is to examine the dependence between uncertainty indices and the uncertainty of cryptocurrencies. The focus is on volatility spillovers between different risk proxy indices: geopolitical events, economic policy, commodity, equity and bond markets, and cryptocurrency uncertainty indices. The spillovers are used in networks, and various centrality measures are calculated to test which risk index or cryptocurrency is leading the market changes. Based on weekly data from April 2014 to March 2024, covering several market ups and downs, it is found that the transmission from uncertainty indices to cryptocurrency uncertainties is rather weak on average, but accelerates during turbulent periods such as the Covid-19 outbreak or the start of the Ukraine war. Overall, we conclude that while cryptocurrency pricing is largely decoupled from economic risk, the ability of the asset class to serve as a portfolio hedge may be limited.

Invited session

Chair: Dogan Keles

1 - Hybrid Electricity Market Models: Combining Zonal and Nodal Pricing for Congestion Management

Endre Bjørndal, Benjamin Fram, Mette Bjørndal

Regulators in Europe are pushing for increased synchronization between European electricity markets. While this market coupling promises higher market efficiency and welfare gains, it also presents challenges for market administrators and grid operators who must manage congestion between market areas.

In this paper, we propose several novel hybrid pricing models for congestion management in electricity markets. Hybrid models manage congestion by allowing certain market areas to use nodal pricing and others to use zonal pricing and have been previously shown to offer significant welfare improvements over zonal pricing models. We present two classes of hybrid models: simultaneous and sequential. Simultaneous models clear the market in a single step where nodal and zonal pricing areas are both cleared at once. Sequential models first clear a fully zonal model, fix the resulting power flow quantities between market areas, and then re-clear the nodal pricing areas in a second modelling step. We also present several subvariants of these models where we aggregate, partially disaggregate, and fully disaggregate the transfer capacities of lines connecting market areas.

2 - The Effects of Multi-Market Participation on Day-Ahead Trading of an Electricity Producer

Helmi Hankimaa, Bruno Fanzeres, Fabricio Oliveira

The green transition has accelerated the expansion of variable renewable energy generation, most prominently wind generation. This significant penetration of wind power amplifies the need for reserve capacity and adjusting commitments close to dispatch. While these needs are recognised, whether current market prices incentivise generation companies to participate in reserve and intraday markets is unclear.

This work investigates whether price signals provide adequate incentives in these markets and how multi-market participation affects trading on the primary market for electricity, the day-ahead market, from a single-agent perspective. To that end, we propose a profit-maximising

offer-strategy optimisation model for a price-taker in the Nordic day-ahead market and a reserve market. Uncertainties in market outcomes, intraday trading opportunities, renewable generation, and imbalance settlement are accounted for.

Incentives for and the effects of multi-market participation were assessed in a case study. Our results indicate that current price signals incentivise multi-market participation, which is seen from an increase in expected profits. We also observed that anticipating reserve and intraday market opportunities had an impact on day-ahead trading. Furthermore, a bias according to expectations regarding the system imbalance was identified. In fact, under certain circumstances, day-ahead offer curves in multi-market offer strategies resembled the use of market power.

3 - Bidding Behavior Analysis in Electricity Markets Using Inverse Reinforcement Learning

Ezgi Polat, Mehmet Güray Güler, Mehmet Yasin Ulukus

In electricity markets, participants employ diverse strategies when submitting their bids. From a realistic perspective, it can be considered that participants aim to increase profitability and thus maintain their market presence. However, unlike profit maximization, participants' bidding behaviors are shaped by considerations like available capacity, market prices, market risk, etc. This research aims to investigate the bidding behaviors of electricity market participants using Inverse Reinforcement Learning (IRL). IRL aims to identify an objective function (reward function) from the historical bidding behaviors of an optimally behaving market participant. In this study, different IRL structures are utilized for linear or nonlinear reward function assumptions. In addition, the bidding behaviors of power plants using different energy sources, such as wind, gas, coal, etc., are comparatively analyzed. The research relies on data sourced from the Australian electricity market.

4 - Modeling and solving the first pan-European Guarantees of Origin market with Artelys Knitro

Stefania Pan, Michaël Gabay

Guarantees of origin (GOs) are a tool to trace and guarantee the renewable origin of electricity. Using GOs enable electricity suppliers to provide specific contracts to customers such as renewable energy contracts or even more specific contract such as German non-subsidized wind electricity. This also encourages investments in renewable energy technologies and provides an additional source of revenues for energy producers. The European Power Exchange (EPEX SPOT) and European Energy Exchange (EEX) have launched in 2022 the first pan-European spot auction for GOs. GOs may differ in issuing country, production technology, subsidy schemes or production month. This auction is uncommon as it offers market participants with the option to bid for products which are either specific or generic, enabling purchasers to express precise requests, stimulate competition and create reliable price indices. Artelys has worked closely with EPEX and EEX in the auction design and was in charge of the development of the market clearing engine. The algorithm has to ensure that various business rules are respected, and to strike the right balance between flexibility, complexity, fairness and intuitiveness. The algorithm objectives are to maximize the social welfare, the traded volume, and to compute all specific and generic market clearing prices. The problem consists in a multi-staged mathematical optimization algorithm which is solved using the state-of-the-art numerical solver Artelys Knitro.

1 - Optimized planning of volunteer first response resources to emergencies

Tobias Andersson Granberg

The number of initiatives involving volunteers contributing to initial response in emergency situations is increasing. Determining which volunteers to alert, and assigning tasks to them, is not a simple question to answer, especially when there are many different types of tasks. Therefore, we develop dynamic models and strategies for task assignment and alerting of volunteer responders. Additionally, we evaluate new alerting strategies using simulation (computer simulation and real-world simulation) to better understand their impact, enabling us to enhance the developed strategies. Drones can also be used to transport equipment to an incident site; for example, drones are used to transport defibrillators to suspected cardiac arrest cases in the Västra Götaland region in Sweden. Since it is crucial for the operation where drones start their journey and that someone is available to use the defibrillator when it reaches the patient, we have developed models for locating drone stations, combining them with models for alerting volunteers. The results show that by joint planning of drones and volunteers, it may be possible to improve the survival probability from out-of-hospital cardiac arrest.

2 - Optimizing the training of community first responders

Brian Overbeek, Rob van der Mei, Caroline Jagtenberg, Pieter van den Berg

Traditional emergency medical services can be expanded by Community First (CFR) systems. In such CFR systems, trained volunteers near the incident location can be dispatched, potentially reducing the emergency response time.

LIVES is an example of such a CFR system; LIVES dispatches volunteers to medical emergencies in (mostly) rural areas of the UK, where the response time of EMS can be rather long. The volunteers of LIVES respond to a wide variety of medical emergencies. However, not all volunteers are qualified to handle all emergencies. Volunteers are classified into different categories based on their medical skills. LIVES provides training to its volunteers to increase their skill level, allowing volunteers to be dispatched to more emergencies as a result. LIVES has a fixed training budget and would like to know how to divide it over its volunteer base. We leverage historical data on incidents as well as volunteer availability, derived from individual sessions in which a volunteer was logged on within the system. Their stochastic availability, combined with a geographically diverse volunteer set, translates into a unique optimization problem: how to spend the training budget in such a way that response times are minimized. In this talk, we present our ongoing work on how to tackle this optimization problem.

3 - Optimizing Emergency Medical Service Capacity to a Mass Casualty Incident: Balancing with Routine Emergency Medical Service Demands

Inkyung Sung, Peter Nielsen

This study addresses the dynamics of an emergency medical service (EMS) system during the response to mass casualty incidents (MCIs), where timely and efficient decision-making is crucial to save more lives. The key decisions to efficiently respond to an MCI with limited EMS resources, such as ambulances and hospitals, include ambulance allocation to the MCI, balancing with response capacity for routine EMS demands, and hospital transportation for MCI victims, thereby avoiding congestion at the hospitals. A mathematical model is developed to represent the relationships between the decisions involved in the MCI response phase and the relevant EMS performance metrics. Based on the model, numerical analysis is conducted with the aim of offering insights into protocol and policy design for EMS systems during the MCI response.

4 - Towards a repository for datasets of mass casualty incidents

Melanie Reuter-Oppermann, Florentina Hager

Many mathematical models and algorithms to address logistics around mass casualty incidents (MCI) have been proposed in the literature. However, hardly any data sets exist that can be used to analyse, validate and evaluate approaches and solutions. As MCI are comparably rare, real-world data is scarce and often very sensitive, making it difficult for

1 - Risk, Uncertainty and AI: non-probabilistic methods for anticipating and preventing AI risks

Vicki Bier, Alexander Gutfraind

The rapid advance of AI has created risks that are difficult to foresee, let alone quantify, making AI risks an area of deep uncertainty. Despite this, researchers have begun applying probabilistic methods to AI risks at a coarse level; e.g., existential catastrophe. This type of analysis may be useful for supporting strategic policy-level considerations, but is not particularly useful for design or operational decisions.

We argue that many practical AI problems could be addressed by drawing from a toolkit of non-probabilistic risk-management methods. There exists a large class of strategies for managing risks that could be utilized to improve AI safety, using methods from fields such as safety engineering, product management, and military planning. These techniques could be used both to anticipate AI risks, and to mitigate AI risks even when they are imperfectly understood or cannot be quantified. These methods range from qualitative fault trees and event trees, to simple but effective solutions like checklists, what-if thinking, and pre-deployment testing (even by non-expert users).

We distinguish between safe design vs. rapid reaction to undesired behaviors. Reactive solutions include contingency planning, monitoring, and anomaly detection. These strategies can also operate in parallel, creating defense in depth. Drawing on these non-probabilistic methods should make it possible to develop safer AI applications, while allowing the field to advance.

2 - A Behavioural Investigation of Feasibility and Demand Uncertainty in Production Planning Systems

Maryam Azani, Lijia Tan, Rob Basten, Ton de Kok

Production planning systems are an integral component in human planners' decisions and, ultimately, joint human-system performance. Although analytically superior systems are known to generate better suggestions, it remains unclear how human planners react to the suggestions and, thus, whether the resulting joint performance is enhanced when using these systems. We examine the impact of different system suggestions on joint performance in a rolling horizon setting with two products and three components under demand uncertainty. We test this in a laboratory environment. We compare human planners' judgemental adjustments and joint performance using system suggestions with different analytical performance (control, Material Requirement Planning, Synchronized Base Stock). We understand that human planners' deluded self-confidence and a desire for control over the system result in adjusting system suggestions regardless of the analytical superiority of the system, which constantly degrades performance. This effect is stronger for systems with superior analytical performance. Additionally, we understand that human planners' judgemental adjustment patterns are different across three systems. We replicate these findings in a field experiment with actual planners.

3 - Multivariate global sensitivity analysis of a coupled climate-economy model

Leonardo Chiani, Emanuele Borgonovo, Elmar Plischke, Massimo Tavoni

We use a novel multivariate sensitivity analysis technique based on Optimal Transport to quantify the sources of uncertainty in future CO2 emissions to help support robust decision-making in climate policy. We apply these methods to an open-source climate-economy model (RICE50+), using the most up-to-date input distributions and long-term projections of key demographic and socio-economic drivers. We assess different scenarios to address different possible futures. We performed the same analysis on the global and regional levels, finding similar patterns but also regional specificities. We show the feasibility of applying new indices to a model with many correlated inputs and a time and region dependent output such as CO2 emissions pathways.

4 - Global Sensitivity Analysis with Optimal Transport

Emanuele Borgonovo

In this work, we present a review of global sensitivity analysis using optimal transport. We describe the properties of the method. The interpretation of the results and the decision analysis implications are thoroughly discussed, also in comparison with other methods developed in the management sciences.

1 - The Team Orienteering Problem with Variable Time Windows: An application for wildfire suppression

Begoña Vitoriano, Bibiana Granda

The Orienteering Problem (OP) is a well-known routing problem within Operational Research, from which various variants have emerged over time. This presentation introduces the Team Orienteering Problem with Variable Time Windows (TOPVTW) as a new variant based on the Team Orienteering Problem with Time Windows. The distinguishing feature of TOPVTW lies in its adaptive time windows, which evolve dynamically according to the solution. This problem arises within the context of spreading processes that need to be contained. An application to wildfire suppression will be presented. In this problem, the spread of fire determines the time windows for brigades to work in a parcel of the landscape or cross through it. Simultaneously, the brigades' work controlling parcels modifies the spread of fire, preventing it from spreading through the controlled area. The aim is to determine the location of the brigades' work and their routes through the landscape to minimize the value of the burned area while maintaining safety measures for the teams. Two alternative mathematical programming models will be shown for this problem, with computational results comparing the solutions.

2 - pyO3F - A python framework for wildfire related optimization

Filipe Alvelos, Marco Henrique Vieira Marto, Isabel Martins, Susete Marques, André Bergsten Mendes

We present a python framework, pyO3F, which aims to support the development of optimization approaches for wildfire related problems. We describe the pyO3F main modules, their interactions, and the information they use to model fire behaviour, fire spread scenarios, and different types of firefighting resources. At the core of pyO3F is the use of the minimum travel time principle in a network with nodes representing locations and arcs representing potential fire transmissions between adjacent locations. Fire spread is modelled as a set of quickest paths with respect to the fire transmission times associated with the arcs (estimated with fire behaviour models). We exemplify

the use of pyO3F in two types of problems: fire suppression and fire-aware forest management. In the former, it is intended to manage a set of available firefighting resources to minimize the impact of fire (e.g. the burned area). In the latter, it is intended to select a set of prescriptions, one for each forest stand, to maximize the net present value of the timber, taking into account bounds on other ecosystem services (e.g. carbon stock) and fire spread simulations.

3 - An extension of the Area Restriction Model

Arturo Annunziata, Matteo Lapucci

The problem of harvest scheduling consists in determining the optimal planning solution selecting from different stands in a forest in a multi-periodal setting. The objective is to maximize the total revenues under some economical and regulatory constraints. This problem involves both financial and environmental considerations. In the latter the main concern is the one of the conservation of wildlife and natural habitats and it results in a restriction on the maximum contiguous area of clearcut regions in a forest. One approach to address this problem is the area restriction model (ARM) an Integer Linear Programming model in which decisions variables are binary variables prescribing the cut of a specific stand in a specific period. In particular the Path formulation of the ARM is an efficient way to manage the maximum clearcut area constraint. In this work an extension of this formulation is presented in which the planner is provided with an additional option to schedule the harvesting. The consideration of some special areas between each pairs of stands in the forest, called buffers, allows for considerable improvements in the optimal value of the objective function and makes the resulting Mixed Integer Linear Programming model more flexible. In fact the introduction of buffers often allows for feasible solutions in scenarios in which the problem would be otherwise unfeasible.

OR Innovations in Policy Making - A

Stream: Soft OR and Problem Structuring Methods

Invited session

Chair: *Irene Pluchinotta*

Chair: *Ine Steenmans*

1 - Integrating Socio-Emotional and Cognitive Perspectives in Causal Loop Diagrams Analysis

Ke (Koko) Zhou, Irene Pluchinotta, Nici Zimmermann

Research on behavior and soft systems emphasizes the role of 'socio-emotional demands' in decision-making processes. Causal loop diagrams, which represent the complex mental models of decision-makers, play a crucial role in achieving a shared understanding of the system elements and boundaries. However, it is not fully understood which elements might be overlooked in the process of reaching a common understanding, and why this occurs. Drawing from critical systems thinking, we propose that during the creation of causal loop diagrams intended to aggregate diverse mental models, certain variables and links might be unintentionally neglected. We introduce the concept of two types of boundaries in these diagrams: structural (the interconnections between system elements) and emotional boundaries (how stakeholders perceive the variables with varying valence and activation). The complex interaction between these boundaries can lead to parts of the system being ignored. Through a case study on sustainable urban development, our research deepens the understanding of how boundaries are compared and elements of the system are marginalized. Our goal is to encourage the integration of socio-emotional and cognitive perspectives in analyzing causal loop diagrams in complex systems.

2 - From Cognitive Maps to Value Trees for Policy Design

Halil Berkay Tosunlu, Joseph Guillaume, Irene Pluchinotta, Alexis Tsoukias

Complex policy issues, decision aiding, and the intricate landscape of conflict transformation and management demand meticulous attention. In this context, our study delineates a structured three-step approach. We first focus upon Conflict Transformation and Management, improving Problem Structuring Methods, cognitive maps, and value trees to address conflict situations and complex decision-making tasks. We prioritize the transformation of subjective insights from Cognitive Maps into structured Value Trees. We then move from decision theory to design theory, where we aim to further enhance PSMs by introducing innovative and out-of-the-box alternatives, with a particular focus on Concept-Knowledge (C-K) theory to create a meaningful connection between PSMs and C-K theory. Finally we discuss how these findings relate to policy design, linking our research to Conflict Transformation and Management within the sphere of public policy.

3 - Multi-objective optimization to support decision making in policy interventions

Laura Selicato, Alessandro Pagano, Estrella Lopez Moya, Manuel Bea Martínez, Andreas Panagopoulos, Vassilios Pisinaras, Flavia Esposito, Raffaele Giordano

The aim of the Water-Energy-Food-Ecosystem Nexus (WEFE Nexus) approach is to overcome the traditional "siloed" approach to natural resources management - i.e. based on sectorial perspectives - ultimately achieving an integrated resources management. In this study, we particularly focus on the support to policy-making in complex Nexus systems, proposing a highly participatory methodology to co-design potential policy interventions capable of achieving sectoral security, while optimizing the Nexus. A System Dynamics Model (stock and flow) that describes the security dimensions was built. We then selected the variables representative of the concept of security, and built the underlying equations, with the idea of evaluating their variation in different political scenarios. Multi-objective optimization (MOO) has been used for identifying and analyzing existing and potential implications and trade-offs in intervention policies. In our framework, we compared two distinct a posteriori MOO methods - pattern search (PS) and the Evolutionary algorithms (EA) - to provide the Pareto front for two intervention areas, i.e., Donana and Pinios (LENSES project). Some hints are given on how this tool turns out to be very useful as a support to decision-makers, to allow accounting for their preferences in the process.

4 - Structuring decision problems and generating alternatives: report of a workshop

Irene Pluchinotta, Ke (Koko) Zhou, Marta Bottero, Alberto Colorni, Chiara D'Alpaos, Alessandra Oppio, Alexis Tsoukias

Problem structuring and alternatives generation are important and highly interconnected stages of decision-making and decision-aiding processes. An ill-formed problem formulation or a limited set of alternatives have a significant impact on the quality of the final decision. This is emphasised when complex multi-actor decisions or policy making need to be supported. Problem structuring methods are largely recognized for their valuable contribution to decision-and policy-making processes; on the other side, the alternatives generation phase is often overlooked in research and practice, leading to unsatisfying decisions. Yet, alternatives are generated before being analysed, explicitly or implicitly, formally or informally.

Within this context, this talk presents the lessons learnt from a collaborative activity carried out with international Operational Research (OR) experts involved in an experimental workshop. The focus of this activity was the problem formulation and alternatives generation phases occurring between a client and six analysts using different OR methods. The objectives of the experimental workshop were to observe and discuss how different approaches deal with structuring decision problems and generating alternatives, and to share experience on procedures which might be transferable. In doing so, the talk catalyses

Flexibility in future energy systems

Stream: Energy Markets

Invited session

Chair: *Henrik Madsen*

Chair: *Mehrdad Pirnia*

1 - Impact of storage flexibility in energy markets under risk aversion

Sining Liu, Martin Densing, Russell McKenna, Giovanni Sansavini

In this study, we explore the role of storage in multi-period risk-averse energy markets. We consider market agents, namely energy producers and consumers, optimising profits across both energy spot and derivative markets. Each agent acts as a price-taker in the environment where the prices are endogenously determined. The energy producers have storage devices and manage energy flows through charging/discharging. We use coherent risk measurement in its dynamic form to model risk aversion. To solve the agents' stochastic optimisation problems, we adopt ADMM (alternating direction method of multipliers) algorithm through decomposition and extend the algorithm to the multi-market framework. A case study is conducted involving conventional power plants, pumped hydropower and consumption, with the focus on peak and based load scenarios. Specifically, we investigate how storage flexibility, encompassing charge/discharge and boundary conditions in storage and capacity constraints, influence agents' behaviours and market outcomes. The relationship between optimal storage strategies and hedging activities in the derivative markets is also examined. Furthermore, we analyse how varying levels of risk aversion affect decision-making processes, along with their effects on prices and profitability.

2 - Modeling electricity consumption flexibility to determine the optimal medium-term electricity procurement for cement producers

Miguel Carrión, Jose Arellano, Álvaro García-Cerezo

With the current economic and energy situation, it's crucial for large electricity consumers to thoughtfully consider their electricity options. This work aims to determine the optimal approach for cement manufacturers to decide their electricity procurement sources. The available options include grid electricity purchase, bilateral contracts, and the utilization of a solar photovoltaic installation and batteries. Furthermore, we analyze the flexibility in electricity consumption by modeling all stages of cement production. The proposed approach is a mid-term decision-making tool considering different sources of uncertainties, formulated through a two-stage stochastic programming approach. To validate our approach, we have conducted several case studies based on a real cement producer based in Spain.

3 - Addressing explicit demand response in a day-ahead electricity market in Italy: Case study on the diving equipment manufacturing sector

Ehsan Manafi, Eduard Bullich-Massagué, Bruno Domenech, Marc Juanpera, Rafael Pastor, Matteo Ranaboldo

Maintaining a balance between electricity generation and consumption is critical for grid stability. While not extensively studied in scheduling problems, explicit (incentive-based) demand response (DR) is an effective strategy to tackle this concern. Here, the ancillary service agrees to customers' proposals to reduce energy consumption during specific time periods. This paper aims to investigate the explicit demand response approach at an Italian company consisting of multiple press machines on the shop floor, specialized in producing diving equipment. A heuristic procedure is developed to propose a baseline production plan and multiple alternative plans, where a subset of machines are deactivated, to provide flexibility services to the market.

The several electricity consumptions profiles resulting from the different production plans will be submitted to the ancillary market. During the production, the ancillary service may request the manufacturer for a transition from the baseline to an alternative production plan, in exchange for an agreed monetary incentive. Hence, the proposed heuristic is applied to assess the effectiveness of the incentive-based demand response strategy in the Italian plant. The results indicate that the proposed heuristic amplifies profitability for both the service provider and the manufacturing system.

4 - Chance Constraint Models for the Operations of Storage Systems in Energy and Reserve Markets

Mehrdad Pirnia, David Fuller, Hassan Shavandi

We present several analytical results for a chance constrained model of electric energy storage participating in both the energy and reserve markets, alongside generation, in the context of a day-ahead unit commitment model. The main source of uncertainty, and thus the reason for a reserve market, is assumed to be imperfect forecasts of wind generation. Although some intuitions in deterministic models remain valid under uncertainty but most of the intuitions and proofs become invalid in the presence of uncertainty, like buying energy at the lowest price and selling at the highest price by the battery when is available for reserves. Therefore, analyzing the unit commitment problem in the presence of wind power uncertainty and inclusion of storage batteries become crucial. We develop two chance constrained models with different features and applications. The results are discussed through a numerical example.

Machine learning and analytics in healthcare

Stream: OR in Health Services (ORAHS)

Invited session

Chair: *Phillips Edomwonyi Obasohan*

1 - Optimizing General Practitioner Appointments with Machine Learning: A Data-Driven Approach

Eric Leung

Global healthcare faces a significant challenge with missed appointments, leading to financial losses and decreased service efficiency. According to the UK's National Health Service (NHS) reports over 300 million missed appointments annually, costing over '216 million. This paper introduces an innovative machine learning-based system for optimizing General Practitioner (GP) appointments, enhancing scheduling by analyzing patterns of cancellations and no-shows. Utilizing both real and hypothetical data, we propose a highly applicable system which employs fuzzy logic algorithm to dynamically adjust GP schedules, prioritizing urgent cases and allowing walk-ins. This approach significantly benefits healthcare providers by maximizing resource utilization and reducing idle time. From a patient's perspective, it ensures better access to care and shorter wait times for urgent needs. Our findings demonstrate the system's potential in offering practical recommendations for managing walk-ins and unforeseen consultations more efficiently, paving the way for improved patient satisfaction and operational effectiveness in healthcare settings worldwide.

2 - Optimizing red blood cell matching policies to reduce alloimmunization in regularly transfused patients

Meryl L. Wemelsfelder, Folarin Oyebolu, Dick den Hertog, William J. Astle, Mart P. Janssen

We propose a method for optimizing daily red blood cell (RBC) matching policies to minimize long-term alloimmunization rates in regularly transfused patients. When antibodies are formed against an antigen, a risk that comes with RBC transfusions, the patient can never be mismatched on that antigen again. Clinical guidelines recommend extended preventive matching for patients at high risk of alloimmunization, such as sickle cell disease patients, who need a transfusion every six weeks. They must be matched not only for major antigens

A, B, and D, but for an additional 5 to 12 minor antigens as well. We use linear optimization for daily RBC matching, including parameters for weighting elements of the objective function. We train machine learning models to predict the long-term outcomes of the matching strategy, then use these models to optimize parameter values. A wide range of potentially optimal parameter values is found, likely a result of the stochastic nature of real-world scenarios, combined with the interplay of factors influencing long-term outcomes. We implemented a selection of these for daily matching, and observed an increased performance for several long-term outcomes with respect to the baseline setting without tuned parameters. The methodology developed in this paper in the context of RBC matching, could also be used in applications where we optimize long-term performance via a parameterized short-term optimization model.

3 - The intersection of sex, age, and household socioeconomic status in the multimorbidity of malaria, anaemia, and malnutrition among children 6-59 months of age in Nigeria

Phillips Edomwonyi Obasohan

Multimorbidity of malaria, anaemia, and malnutrition (MAMM) is a condition an individual cohabits with two or more of these health outcomes and is becoming an emergent public health concern in sub-Saharan African countries. In addition, the independent associations of child's sex, age, and socioeconomic disparities with child's health outcomes and MAMM have been established in literature. But, the effects of the intersection of these factors, while accounting for other covariates have not been studied. Therefore, this study aimed to determine how child's sex, age and socioeconomic status interact to explain the variations in MAMM among children age 6-59 months in Nigeria. Data from the 2018 Nigeria Demographic and Health Survey was used. A multilevel mixed effect ordinal logistic regression model was used. Five models were created in this scenario. Model 1 is the interaction between child's sex and wealth status; model 2, child's sex and age; model 3 is between child's age and wealth status; model 4 has the three 2-way interactions of child's sex, age, and household wealth status, and model 5 includes model 4 and the 3-way interactions between a child's sex, age, and wealth quintiles. Model 3 was however the model of best fit compared with other models. So, the two-way interaction effects of a child's age and wealth status are relevant in the model prediction. Thus, the variation in MAMM over a child's age differs depending on the household wealth quintile.

1 - Development of simulation models in Excel for conducting inventory analyses in continuous time

Christian Larsen

When teaching a course in Inventory Management at the graduate level it is inevitable that the lecturer needs to use simulations for pinpointing some of the more complex matters that, cannot adequately be covered by any analytical formulas. The issue can then be whether the simulation program used in the course, should be a specialized discrete event simulation program like Arena, or it could be done in Excel, or maybe using both tools in the course. When teaching business students who are not that well acquainted with a program like Arena it can be of advantage to use Excel, entirely. However, Excel is at first glance mostly geared for working in discrete time, as it does not have any sort of event calendar file. The presentation will demonstrate how it is possible, by using some simple modeling effort, to conduct inventory analyses in Excel in continuous time.

2 - Conceptual Simplification: A New Method for Analysis, Learning and Memorisation of Post-Tonal Piano Music

Laura Farré Rozada

There is a gap in music performance, education and psychology in terms of memorisation training for post-tonal piano music. Despite the repertoire spanning over 100 years, pedagogues and professionals still lack effective tools for developing this skill. Existing research mostly focused on observing practitioners' behaviours during practice, to understand how these prepare for a memorised performance. However, a systematic method for effective memorisation is not provided. This paper discusses Conceptual Simplification: a new method for analysis, learning and memorisation of post-tonal piano music. This presents a novel implementation to musical memorisation building on mathematics and computer science to improve human memory and musical performance. However, Conceptual Simplification does not require previous scientific training to be successfully implemented and works for different learning styles and types of complexity. It could also be adapted to other instrumentalists, singers and conductors; and musical genres; and presents enough flexibility for other practitioners to incorporate additional strategies. The method also assists in preventing performance anxiety and reducing the potential for injuries that usually result from repeated practice. The method's systematic approach engages conceptual memory and reasoning, leading to more confident memorised performances, while needing less repetition during practice.

3 - Leveraging Virtual Reality for Soft OR Education

Katharina Burger

Traditionally, Soft OR is operationalised in in-person workshops, where participants interact with a range of tools, which may include modelling software but are often just flipcharts and sticky notes. More recently, Soft OR interventions have been conducted in 2D online spaces (e.g. via Zoom and using Miro). However, considering the growing potential of embodied interaction in immersive virtual reality (VR) spaces, what are the opportunities and challenges of using 3D VR spaces as part of Soft OR education? Drawing on empirical data from student participants interacting in immersive virtual environments (IVEs), we differentiate between challenges and opportunities pertaining to technology appropriation and in-IVE interaction for Soft OR. We conclude by reflecting on the broader implications for creating inclusive hybrid futures of OR education.

4 - OR in an wind blade production unit: an assignment problem formulation developed by undergraduate students

Ana Raquel Xambre, Carolina Correia, Hugo Malcato, Mariana Pinto, Xavier Pinto

The Industrial Engineering and Management (IEM) undergraduate students, from the University of the Aveiro, have to develop a project in their last semester. The purpose is for them to apply the knowledge and skills acquire throughout the IEM program to a complex problem, while also developing other skills like critical thinking, Problem solving and team work. One of the problems, addressed by a group of four students, originated from a wind blade production unit, specifically in the part of the process where the blade is molded using different sized fibers. The fibers have to be transported in carts that are positioned near the blade, so the goal is to assign them to the carts, as well as the carts to the locations near the blade, so as to minimize the distance of the fiber to the respective point of use. The work developed allowed the students to comprehend a complex industrial problem, while also using OR and thus understanding how it can be put in practice, in order to help organizations with their problems. The results of the work were very useful for the company, helping them improve their performance in this process. It was also very positive for the students since it contributed to a more practical vision of the use of OR. It is also expected that this work, and other similar developed by undergraduate students, may become examples for future students, helping them cross that same bridge between theory and practice.

DEA in healthcare

Stream: OR in Health Services (ORAHs)

Invited session

Chair: [Erhan Berk](#)

1 - Performance of private healthcare sector and the role of public policy: A study of India using Data Envelopment Analysis and Gradient Boosted Trees

Aishna Sharma, Rahul Nair

The demand for healthcare services provided by Indian private hospitals has increased, which makes it imperative to assess their performances. We also assess the impact of public spending and governance on their performances. We first estimate output oriented and input oriented technical efficiency scores of 163 private hospitals for the year 2022-23 using Data Envelopment Analysis. Expenditure on compensation of employees of hospitals, on power, fuel & water, on repairs and maintenance and Net Fixed Assets are inputs, with Total Income as output. After this, we estimate Gradient-Boosted Tree Classifier (GBTC) taking output efficiency score as dependent variable and public spending and governance factors as independent variables. Results show, on an average, the output oriented technical efficiency score is 0.66 and the input oriented score is 0.64. Big hospitals outperform small hospitals by 16 percentage points. Extent of misutilisation or underutilization of financial resources is greater than the extent of inadequacy of services delivered by the hospitals. In GBTC analysis, with output oriented scores as dependent variable, the most important features with a Mean Decrease in Impurity greater than 0.1 are Voice and Accountability score, Revenue Expenditure on Education, Revenue Expenditure on Water supply and sanitation and Revenue Expenditure on Urban Development. We recommend better governance structure; increased public spending and periodic audits of private hospitals

2 - A Four-Step Roadmap for Measuring and Maximizing Patient Value in Healthcare Using Data Envelopment Analysis

Joke Borzée, Brecht Cardoen, Filip Roodhooft, Laurens Cherhye, Bram De Rock, Jo Lambert

Value-Based Healthcare (VBHC) is a framework that aims to shift the focus of healthcare systems from increasing volume to enhancing value, which is defined as the ratio of patient-relevant health outcomes to the costs of achieving them. This framework can help to address the rising healthcare expenditures by encouraging health facilities to organize around the patient and pursue the goal of maximizing patient value. However, measuring patient value is still challenging due to its multidimensional nature, impeding the implementation of VBHC. In this research, we therefore propose a four-step value measurement roadmap, which leverages operations research techniques to convert the value equation into a single value score for each patient, using Data Envelopment Analysis (DEA) as the main tool. This novel application of DEA enables a holistic benchmarking of patients by directly linking outcomes to costs, unveiling the relative value that is created. We illustrate how the roadmap can be customized and applied to different health contexts, using the case of psoriasis as an example. After collecting individual health outcomes and calculating treatment costs for 109 psoriatic patients, we construct a value frontier which reveals substantial differences in created value within the patient population. Subsequent detailed analysis of the value scores offers insights into the drivers of value creation, supporting health professionals to optimize healthcare delivery.

3 - A new classification of data envelopment analysis applications in hospitals.

Frederic Vanswijgenhoven, Brecht Cardoen, Paul Gemmel

Healthcare providers are continuously striving to organize care and cure more efficiently while maximizing outcomes for the patient. Benchmarking is seen as an important instrument to improve processes and the organization of care on the level of hospitals and processes within these hospitals. Data envelopment analysis (DEA) shows to be a successful method to facilitate such benchmarking, thanks to its ability to combine inputs and outputs into a single efficiency score. However, the method might not have been used to its full advantage given recent evolutions in the healthcare landscape. By means of a systematic literature review, including 498 articles for the period 1980 till now, we developed a classification system to position DEA benchmarks. Only a very small number of studies can be classified as DEA applications aimed at investigating process flows within and between hospitals, compared to a more traditional static or silo-oriented approach. This opens a future research agenda to investigate efficiency when care processes extend beyond multiple units within a hospital, or even across multiple hospitals which we now see emerging by formation of hospital networks and systems. In this presentation, we break down the DEA literature on different new dimensions and show a clear imbalance in problem settings studied by the academic community, highlighting new opportunities towards problems practice is currently challenged with.

4 - Evaluation of Healthcare Systems during COVID-19 Pandemic in Türkiye

Erhan Berk

COVID 19 infection spread to the whole world in a short time at the end of 2019 and affected the health system of many developed and developing world countries negatively. Türkiye was one of the most negatively affected countries in the world. In this paper we evaluated the performance of 81 provinces and 7 regions of Türkiye against COVID-19 disease using efficiency score which was calculated by data envelopment analysis (DEA) and compared the efficiency score with the different models which are used to evaluate the efficiency of healthcare system. We took input parameters as public health expenditure in a million, number of hospitals, number of hospital beds, percentage of health workers, population density, and number of infected. We divided output parameters into good and bad categories such as the number of recovered are taken as good output. The number of death is taken as bad outputs. Finally, the provinces and regions are ranked with the super efficiency score and evaluated benchmarking for each states and regions.

1 - Optimising Food Bank Operations: A Multi-Objective Approach for Improved Nutrition, Equity, and Variety

Pol Gil-Figuerola, Marc Juanpera, Albert Soler-Noguera, Laia Ferrer-Martí, Rafael Pastor

Food banks play a crucial role in facing food insecurity that affects millions of people worldwide. These organisations receive donations and distribute them to vulnerable families, usually through standardised food baskets. Food banks increasingly prioritise nutritional adequacy, food assortment diversity, and equitable product allocation. However, the food baskets may lack sufficient and balanced nutrients, and the family nutritional requirements, which depend on the sex and age of its members, are not considered in detail. In this study, we propose a multi-objective linear program to optimise the food allocation problem from food banks to beneficiaries. We employ a Thresholded Lexicographic Ordering approach to consider the following objectives, in

order of importance: 1) maximise the nutritional coverage of the least covered nutrient-beneficiary pair, 2) maximise the variety of products in food baskets, and 3) minimise the total inequity. The model also considers the specific nutritional needs of the beneficiaries according to their sex and age, as well as the incompatibility between certain food products and beneficiaries due to dietary restrictions. We applied the model to a Catalan food bank case study, and our solutions led to significant improvements in all three objectives compared to the baseline solution.

2 - Developing a knowledge base for the Sustainability Assessment of urban projects: the GLOSSA project

Francesca Abastante, Beatrice Mecca

In line with the 2030 Agenda, measurement through indicators is recognised as a mean to overcome economic, social and environmental challenges in favour of sustainable development. In this context, the SDG11 with its indicators constitutes the starting point for monitoring and implementing urban sustainable development. However, there is a need for measurements going beyond conventional statistics, including data generated, collected and stored by governments as well as those provided by external data sources. In this context, the present research shows a literature review of indicators useful for measuring and evaluating urban sustainability. More specifically, this research aims to: i) build a framework of the official SDG11 indicators at a global, European and Italian national level; ii) identify innovative and operative indicators related to SDG11 proposed in the scientific literature, in the Sustainable Development Strategies produced at the Italian level and in the Sustainable Assessment Tools; iii) provide a set of indicators relevant and useful both for monitoring urban areas and for constructing and evaluating projects. The research result constitutes the first theoretical preliminary step of the research Project of Relevant Interest (PRIN) called GLOSSA (A GLOcal Knowledge system for the sustainability assessment of urban projects).

3 - Estimating Urban Solid Waste Generation for Collaborative Collection Routes using Spatial Analysis and Machine Learning

Carola Blazquez, Victor Silva

In the last decades, there has been an increasing generation of solid waste in urban areas, imposing an environmental, economic, and social burden worldwide. Thus, there is a need to estimate solid waste generation rates for obtaining efficient collection routes and itineraries, particularly when two or more communes decide to collaborate their resources (e.g., vehicles and staff), in order to reduce costs and CO₂ emissions, and increase equitable workload. This study performs spatial analysis using census data, and historical data based on daily GPS measurements and tare weights (tonnage) of collection vehicles in two communes in Santiago, Chile to identify collection zones and estimate initial solid waste generation rates at the street level. Machine learning techniques are applied to predict daily solid waste generation rates using demographic characteristics, land-use, socioeconomic status, and weather information, which are subsequently tested with the initial solid waste generation rates estimations. Prediction results are promising when compared with these initial estimations. Our results provide important insights for supporting the optimization of collaborative collection truck routes among different communes in urban areas.

4 - Enhancing Infrastructure Decision-Making in Smart Cities: A Support Methodology

Pedro Palominos, Diego Cabrera, Luis Quezada, Astrid Oddershede, Valerio Salomon

The challenges posed by urban growth and development are indeed significant world-wide. As cities expand, they grapple with issues related to space, resources, and facilities. The migration from rural to urban areas exacerbates these challenges, leading to increased demand for services such as energy, sanitation, and mobility. Pollution and other environmental problems also arise due to rapid population growth in urban centers. Traditionally, decision-making in municipalities followed top-down approaches, often overlooking the perspectives and desires of citizens. However, a paradigm shift toward Smart

Cities (SC) emphasizes multi-stakeholder involvement and shared visions. To address this, a novel decision-making methodology is proposed, integrating the needs of various stakeholders, including citizens. The stages of the methodology are a) SC Paradigm: Which emphasizes sustainable development, green growth, and collaboration among stakeholders; b) Survey-Based Approach: The process begins with a survey to capture community needs. This data collection phase is crucial for understanding the diverse perspectives within the community; c) ELECTRE: a decision-making technique, is employed to formalize and prioritize these needs. It balances different interests and helps optimize project design. This methodology was applied to a neighborhood in the city of Santiago de Chile, generating solutions to the main problems faced by residents of the sector.

OR in Electricity Markets

Stream: OR in Energy

Invited session

Chair: *Ruth Dominguez*

1 - Analysing load curve variations in the energy transition - a simulation approach

Maritza Jimenez, Carlos Jaime Franco, Isaac Dyrer

The energy transition has implied changes in the behavioural dynamics of the electricity market participants, both from the energy supply and demand perspective. In this regard, it is important to analyse the possible market effects of these changes in the medium and long term. Thus, simulation is presented as a relevant tool for analysis as it allows us to explore the effect of pattern changes based on possible future scenarios. This paper uses the system dynamics simulation approach to evaluate the effect of changes in demand-side consumption dynamics in developing economies by assessing the load curve. The results show that some demand-side management alternatives have greater impacts than others on the load curve behaviours and that the combination of different participation alternatives could have challenging contributions to the technical performance of the intra-day market.

2 - Multiobjective approach for the design and operation of energy communities

Bruno Domenech, Ángel David Téllez-Macías, Marc Juanpera, Antonin Ponsich, Matteo Ranaboldo

Energy communities (EC) using renewable sources are a way to achieve energy transition, assigning an active role to end-users (called prosumers). Every prosumer is an electricity consumer and producer, exchanging electricity with other prosumers and the grid. EC are gaining attention in Europe among researchers and the industry, thanks to their economic and legal recognition within the national regulations. The design and operation of EC is a complex combinatorial optimisation problem, where several objectives are to be accounted for: economic, to ensure cost savings, environmental, to take profit of renewable sources, and social, to achieve equity between prosumers. In this work, a multiobjective (MO) mathematical model is developed for the design and operation of EC, determining the location and size of equipment (renewable generators and batteries) as well as the electricity exchanges between prosumers and the grid. A correlation analysis between the solutions obtained from the individual optimisation of several economic, environmental and social objectives is performed in order to select a reduced set to be included in the MO model. Through a simple approach based on ϵ -constraints, an approximation of the Pareto front can be identified, constituting a set of alternative configurations among which decision-makers may select their preferred one.

3 - Optimal participation of wind producers in the continuous intraday market: a multi-stage stochastic approach

Ruth Dominguez, Miguel Carrión, Giorgia Oggioni

Flexible mechanisms, in terms of both hardware and market rules, are required to ensure the economic, technical, and environmental sustainability of renewable-dominated electric energy systems. Short-term markets such as intraday markets are very important for wind and solar photovoltaic producers since the prediction of their power generation is more trustable just a few hours ahead of the actual energy supply. In this work, we tackle the problem of a wind power generator that aims at deciding the offers to be made in the continuous intraday market taking into account the possibility of participating in consecutive trading floors, such as in the auction-based intraday market and the balancing market. The model is formulated as a multi-stage stochastic programming problem considering the uncertainty of the wind power availability, the electricity prices in each trading floor, and the probability of acceptance of the offers in the continuous market. The CVaR is introduced in the formulation to control the risk level of the solution. The model is tested with real data from the Spanish power system. The scenarios of wind power at each decision stage are generated considering the evolution of the forecast error distribution according to the time spanning between the offering and the delivery time. Numerical results of different sensitivity analyses will be presented.

4 - Modelling balancing service provision in 5th gen district heating systems

Erik Fröhlich, Kerem Öncel, Annette Steingrube

5th gen district heating systems are bi-directional low temperature district heating and cooling networks with decentral generation units. They are well suited for providing flexibility to the power grid. A case study has been performed to model the flexibility such a system can offer. The energy system is represented as a linear optimization problem, that has been extended to model bi-directional flows within the district heating network in the form of energy balances. For the purpose of modeling flexibility provision in the form of balancing services, a two-stage stochastic optimization approach has been developed. The first stage represents planned operation without offering flexibilities, in the second participation on the control reserve market is modeled. Call probabilities for energy bids are implemented as randomized binary series. This concept is aiming at ensuring that the optimization model cannot apply perfect foresight of called balancing services, but a better representation of actual operation is achieved. Due to uncertainties of price development in balancing markets a sensitivity analysis w.r.t balancing service remuneration is conducted, yielding crucial tipping points at which capacity planning and operation in the considered energy system is altered to reduce system costs through providing flexibilities. Challenges resulting from the simplified representation in a linear optimization model are analyzed and suggestions for solution approaches formulated.

employs system dynamics modelling and scenario simulation to comprehensively analyse the project's contributions to key UN Sustainable Development Goals related to developing access to education, food, health and supporting local families. This project will explore critical factors impacting the initiative's success, including infrastructure development and educational resources, community livelihood uplifting, food and healthcare provision. Through system dynamics lenses, we explore the complex interactions among these factors and their combined effect on elevating the local communities. Preliminary findings suggest that the Roof of Africa Project offers a transformative and replicable model for tackling the multi-dimensional challenges of sustainable development in impoverished communities.

2 - Can justice be profitable? The benefits of balancing equity and equality in optimization models

David Rea, Leonardo Lozano, Craig Froehle

Employees care about being treated fairly and will react strongly to perceived unfairness. As such, organizations are increasingly seeking ways to incorporate employee-centric principles in their decision-making processes. This presents the challenge of balancing two sets of trade-offs: the organizations well-being versus their employees, and their employees' desire for equality versus equity. Ensuring these tradeoffs are consistently balanced according to the organization's values at the scale and speed of modern business requires an algorithmic approach. The increasing use of algorithms to guide such value-driven decision-making necessitates a better understanding of how these elements should be integrated within decision-making models. This research explores these complex trade-offs computationally by modeling two representative case studies: a synthetic gig-economy package delivery problem and an empirical interhospital patient transport problem, both of which are NP-hard. One key observation is that certain combinations of functions in the model objective lead to opportunities for organizations to perform better while also representing fairness more precisely. We also find that the effects of trade-off parameters are partially determined by both their relative levels and the functions used in the objective. These and other observations offer guidance for practice while also motivating future research to help fully explore how these concepts shape decision-making.

3 - Model Predictive Control to organize the first vaccination wave during an epidemics (Application to COVID-19 for Wallonia - Belgium)

Morgane Dumont, Candy Sonveaux, Mirko Fiacchini

In case of a new epidemic, decision makers have huge responsibilities in terms of economic impact and public health security. When a vaccine becomes available, they need to strategically define who is going to be vaccinated and when. Moreover, the strategy could need an adaptation after a few days or weeks to be as effective as possible. We propose to use the Model Predictive Control method in order to have a dynamical choice of who is vaccinated and at which moment (with a maximum number of total daily vaccinations). This method starts from the knowledge of the evolution of the disease without any vaccination and proposes a strategy over a fixed prediction horizon by iteratively adjusting the control inputs (vaccination) based on the ongoing system feedback to optimize the performance (minimize the number of dead individuals). To simulate the disease spread, we consider a compartment model including the susceptible, infected, recovered and deaths compartments. The proposed method is illustrated thanks to data about the COVID-19 in Wallonia (Belgium) and the resulting strategy campaign is compared to the strategy really adopted by the government (decreasing order of ages). We show that the two types of campaigns gave similar results in terms of number of deaths and infected, but the Model Predictive Control approach consumes only 63.95% of the vaccines used by the decreasing age strategy. It is thus economically very interesting.

4 - The Hybrid Hospital: Balancing On-Site and Remote Hospitalization

Noa Zychlinski, Gal Mendelson, Andrew Daw

We study the dynamics of hybrid hospitals offering on-site and remote hospitalization through telemedicine. These new healthcare models require efficient operational policies to balance costs, efficiency, and patient well-being. Our study addresses two primary operational questions: (i) how to direct patient admission and call-in policies based on

1 - The Roof of Africa Project: scenario simulation for supporting sustainable development in Sub-Saharan Africa

Genuine Mwashia, Yavora Rosenova, Penka Petrova, R. M. Kazakov

The Roof of Africa Project is an initiative aimed at promoting sustainable development in Tanzania, focusing on access to education, food, health, and family well-being. Our methodological approach

individual characteristics and proximity and (ii) how to determine the optimal allocation of medical resources between these two hospitalization options. We develop a model that uses Brownian Motions to capture the patient's health evolution during remote/on-site hospitalization. By optimizing call-in policies, we find that remote hospitalization is cost-effective only for moderately distant patients, where the call-in threshold has a non-monotonic relationship with travel time. The impact of scarce resources is reflected through simultaneous increase of both remote and on-site costs by the same value, without altering the solution structure under abundant resources. Contrary to the widely held view that telemedicine can mitigate rural and non-rural healthcare disparities, our research suggests that on-site care may actually be more cost-effective than remote hospitalization for patients in distant locations, due to increased risks for remote patients who are called in to the hospital. This may be of particular concern in light of the growing number of "hospital deserts" amid recent rural hospital closures.

Energy sector coupling, optimization and equilibrium

Stream: OR in Energy
Invited session

Chair: Trine Krogh Boomsma

1 - Solving Equilibrium Problems in Infrastructure using the Difference of Convex Functions Algorithm

Steven Gabriel, Dominic Flocco, Trine Krogh Boomsma, Martin Schmidt, Miguel Lejeune

We describe a novel application of the difference of convex function algorithm (DCA) to a variety of equilibrium problems using the mixed complementarity problem (MCP) format. These problems involve bilinear constraints, i.e., complementarity and can be approximated iteratively via convex subproblems using DCA. We develop the necessary theory to make this possible and showcase how it works on several MCPs in energy and other infrastructure.

2 - Addressing Non-Convexities in Sector Coupling Problems via the Difference of Convex Functions Algorithm

Dominic Flocco, Steven Gabriel, Trine Krogh Boomsma, Martin Schmidt, Miguel Lejeune

We present the difference of convex functions algorithm (DCA) applied to a variety of non-convex optimization problems arising in energy sector coupling and equilibrium problems. Non-convexities emerge frequently in many energy models, such as through bilinear terms, integer constrained variables and non-convex quadratic constraints. Recently, DCA has proven effective in solving such problems by linearizing non-convex terms and converging to an optimal solution iteratively by solving convex subproblems. In our work, we use DCA to solve a wide range of non-convex problems, such as linear complementarity problems, mixed integer linear programs and quadratic programs with non-convex quadratic constraints. We demonstrate the effectiveness and versatility of DCA by applying it to a variety of energy models, such as the unit commitment problem, district heating networks and energy market equilibrium problems.

3 - A New Strategy for Solving Cournot Games

Nena Batenburg, Trine Krogh Boomsma

It is well known that Cournot games involving heterogeneous players with affine and decreasing demand functions and convex quadratic production cost functions can equivalently be cast as a mixed linear complementarity problem or a quadratic optimization problem (QP). Market equilibria can thus be computed using a complementarity solver

or, more efficiently, a convex optimization solver. When studying such games, it is common to aggregate the consumers and substitute their inverse demand function to eliminate the market price. We argue, however, that the market price should be treated as an explicit variable that is central to the game. We show that the problem can be reformulated as a fixed-point problem (FPP) for the price only, thereby greatly reducing its dimensionality. The FPP can therefore be solved even more efficiently than the QP and also yields a more accurate solution. The FPP can be generalized to spatial games and games involving multiple commodities. We envision that this could vastly improve solution efficiency and accuracy when incorporated into dynamic or multilevel games. We finally consider a Cournot game across the markets for two commodities that may be converted into each other. The FPP formulation reveals the structure of the equilibrium and allows an analytical stability and sensitivity analysis. We find that market imperfections in either of the markets extend to the opposite market and may significantly reduce the welfare gains from market coupling.

4 - Benefits and challenges of soft-linking for large-scale energy system modelling

Mathias Berg Rosendal, Jean-Marc Janin, David Pisinger, Rasmus Bramstoft, Marie Münster

Computational tractability remains a significant challenge in modelling large-scale, sector-coupled energy systems. This study investigates the soft-linking of models to broaden the analysis scope while maintaining practical computation times. A case study is defined because soft-linking applications are unique to the specific research question. Resource adequacy assessment is therefore defined as the scope in a bidirectional coupling of Balmorel (which performs investment and dispatch on time slices) and the stochastic dispatch model, Antares, which optimises dispatch in multiple weather years with hourly resolution. The models are fully harmonised in terms of data, geographical granularity and level of sector-coupling in a pan-European context. The bidirectional soft link is analysed by comparing computation times at different temporal aggregation levels with the objective of finding the least-cost system with the lowest loss of electricity and hydrogen load. A higher degree of aggregation leads to lower computation times per iteration but more inadequate systems. Thus, more iterations are required to adjust investments. The opposite is valid for a less aggregated approach. A discussion is carried out of the different methods used to signal the need for more investment in carrier transmission, generation capacity, etc., and a conclusion on the benefits and challenges of soft-linking is derived from these findings.

1 - An emergency supply policy for an inventory replenishment model with returns and partial backorders

Yonit Barron, Netanel Drezner

This paper studies a continuous-review inventory replenishment model with a limited storage capacity S in an uncertain environment. We assume that the demands and returns follow independent Poisson processes. We further assume a random shelf life, a random lead time, and early loss. The storage is managed according to the base-stock (S, s) policy for s_0 . In case of overstock, each returned item exceeding S is transferred to a foreign facility. If during the lead time a demand reaches zero stock, we consider two alternatives: either allow partial backordering up to L_B items, beyond which the unsatisfied demand is lost, or call for an immediate and costly emergency supply up to level 0

2 - Inventory Management for an Omnichannel Retailer under Product Returns

Esra Gokbayrak, Berk Deniz, Enis Kayis, Refik Gullu

Fast fashion brands seamlessly integrate various sales channels to create a cohesive shopping experience. This seamless integration extends to the handling of product returns, ensuring that customers experience consistent policies across all channels, thereby enhancing overall satisfaction and retention. Particularly during peak shopping seasons and special occasions, consumers value the convenience of returning products to any store within the brand's network. However, the growth of applying omnichannel retailing has also led to an increase in product returns, posing challenges for inventory management and environmental sustainability due to unsold merchandise. This paper presents a solution for inventory management, considering the complex dynamics of omnichannel systems and the unique challenges generated by high return rates. Using dynamic programming, we formulate a model that optimizes pre-season order quantities for online warehouses and transshipment quantities to brick-and-mortar stores during the selling season. Our sensitivity analysis offers valuable insights for retailers seeking to balance profitability with environmental responsibility in the face of evolving consumer preferences and market dynamics.

3 - A capacity reservation contract for WEEE reverse supply chains

Jenny Andris, Christoph Schwindt

We consider a reverse supply chain for waste from electrical and electronic equipment (WEEE). In Europe, the manufacturers of EEE products are in charge of collecting WEEE and feeding it back into the production cycle. Manufacturers generally appoint collection companies to assume these duties. According to German legal regulations, the clearinghouse Stiftung Elektroaltgeräteregister EAR continuously allocates returned WEEE to the manufacturers based on their registered sales tonnage. In this talk, we focus on long-term contracting between a collector and a manufacturer. We propose a capacity reservation contract, which protects the collector's investment in capacity extension from the risk incurred by uncertain future order volumes. The contract parameters of the collector, who is in the position of a Stackelberg leader, include the capacity allocated to the manufacturer, the option price, the exercise price upon activation of the option, and the per-unit fee for extra short-term orders placed within the agreed capacity. The manufacturer optimizes the number of options bought subject to an upper bound on the value at risk and accepts the proposal if it provides the reservation utility from competing offers. We show that the contract is guaranteed to coordinate the dyadic supply chain under plausible assumptions. Numerical examples illustrate that the optimal exercise price can be negative, which due to EAR's role as an intermediary, does not impair incentive compatibility.

4 - Optimal Product Return Insurance

Gokce Esenduran, Paolo Letizia, Anton Ovchinnikov

In response to the high cost of returns, some firms stop a free returns policy, but give their customers the option to purchase return insurance, which provides customers with the option to return items and receive a refund. We study how to design the return policy and insurance optimally.

1 - Optimal design of socially sustainable raw material supply chains

Lea Franze, Karsten Kieckhäfer, Bruna Mota, Ana Barbosa-Povoa

Driven by due diligence requirements, social sustainability aspects receive more attention in global supply chains. In the automotive industry, e.g., companies search for sustainable supply sources, engage in supplier development, or invest in raw material mining projects to meet social standards. In current research on strategic network planning, however, social sustainability is rarely studied, and often approached in a simplified manner. To address this gap, we develop a novel network planning approach that combines social life cycle assessment, activity analysis, and mixed-integer linear programming. The model particularly decides how much raw material to source from multiple sites, which may operate at different levels of costs and social risks. To meet certain social standards and fulfill demand, different measures are available: commitment to long-term contracts with suppliers, investment in mining projects, and implementation of social development measures. The costs associated with these decisions are minimized in an economic objective function, while social risk is limited by additional constraints. The approach is applied to raw material extraction in the supply chain of lithium-ion batteries for electric vehicles. The analyses show the trade-offs between the sourcing decisions to meet social standards. In cobalt mining, e.g., investing in mining projects in Australia can reduce the social risks associated with sourcing cobalt from long-term contracts in the Congo.

2 - A Model to Diversify the Import of Green Hydrogen

Louis Vincent Sroka, Frank Meisel

Hydrogen, particularly 'green hydrogen' generated from renewable feedstock, is a promising alternative to fossil fuels for decarbonizing the transport and energy sectors. However, achieving a sustainable energy economy based on green hydrogen poses significant challenges due to limited resources and production capacities in many countries. The discrepancy between high demand and low self-supply has to be compensated through imports. Since overreliance on a single exporting nation can lead to geopolitical, financial, and moral complications, the import of green hydrogen should be diversified. In contrast to only regarding parallel bilateral imports, a multinational transportation network offers potential cost reduction through consolidations in production, conversion, and transportation. We propose an optimization model for such a multinational import network for green hydrogen, that considers import diversification as well as factors like transportation losses and conversion efficiencies. Using Germany as a case study, we demonstrate how enforced diversification impacts sourcing decisions and overall costs to further emphasize the trade-off between resilience and cost-effectiveness. Furthermore, we highlight how reducing losses of liquid hydrogen during transportation (through advancing storage technologies) could further diminish the hydrogen price.

3 - Sustainable Planning Optimization in Phosphate Open Pit Mines: Exploring Extraction Routing Impact

Bassma Azzamouri, Ahlam Azzamouri, Agnes Gorge

This paper deals with sustainable production in the mining industry. It aims at planning production activities in Open Pit Mines (OPM) of phosphate while considering the impact of extraction routings (ER), in ensuring the necessary diversity of minerals while preserving rare ones. Planning production activities in phosphate OPM for tactical/operational levels consists of selecting the extraction zones, and blocks, machine allocation, and ER choices. Several researchers have worked on machine allocation and block and zone choices, but less attention was given to the ER impact, especially in ensuring the balance between managing the Supply Chain (SC) efficiently and high-quality phosphate preservation. These ERs consist of extracting non-mineral (waste) layers with mineral ones or independently, controlling minerals' characteristics. We focus on a real case of a SC composed of several OPMs where a unique ER is adopted, making satisfying customer requirements challenging with excessive use of high-quality minerals. For this reason, we first conducted an exploratory study to understand the impact of ERs on OPMs. Second, we developed a MILP model to select the optimal ER to adopt. The model provides the corresponding production program of those mines, defined by the quality, volumes,

and lead time of phosphate. The results shed light on the difference between the production programs resulting from the use of each ER and the balance ensured between efficiency and sustainability

4 - Multi-layer Supply Network Dynamics and Resilience in the Copper Industry: A Complex Network Theory Analysis

Qiyang Liu, Peter Adriaens

Copper, an essential mineral for renewable energy technologies, faces significant supply chain disruption risks due to its uneven global distribution. This research focuses on the vulnerabilities within the copper industry's supply chain, which is extensively interconnected from the extraction of raw materials to the production of finished goods.

This study leverages complex network theory to develop a weighted, multi-layer supply chain network model at the firm level within the copper industry, utilizing real-world data from the FactSet Supply Chain Relationship database. It examines the network's structural characteristics and employs degree-based removal strategies to simulate targeted attacks on the network, offering insights into its robustness.

This study enriches the literature by providing an in-depth analysis of the copper supply chain at the firm level, employing dynamic risk transmission modeling to explore supply risks across firm, industry, and regional levels. The study not only identifies vulnerabilities but also proposes strategies to enhance network resilience. Through this comprehensive framework, we offer new insights into mitigating supply chain vulnerabilities in the copper industry, highlighting the critical role of network structure and interdependencies in supply chain resilience.

1 - Solving a VRP in the energy sector through tabu search with a double neighborhood

Paula Amaral, Ana Mendes, Miguel Espinosa

This presentation deals with the distribution of products in the context of an energy company. This problem can be modeled as a Vehicle Routing Problem (VRP) with several complexities like: time windows, different vehicles, several products, among others. The urgency of optimizing energy transportation cannot be overstated, given the rising global demand for energy resources. Tabu Search is a powerful meta-heuristic algorithm commonly used for solving combinatorial optimization problems. Its adaptability and efficiency make it well-suited for a variety of applications, as the VRP, for identifying good vehicle routes. However, like any optimization algorithm, Tabu Search faces challenges, and one of the main issues is dealing with local optima where the algorithm might get stuck. In scenarios with numerous local optima, Tabu Search may struggle to escape these regions of attraction efficiently, leading to slow convergence and potentially sub-optimal solutions. In response to this challenge, we propose a novel double neighborhood strategy employing opposite optimization directions (minimization and maximization). The maximization component is strategically employed to facilitate the escape from local minima.

We showcase the application of this approach to a challenging and intricate VRP problem. Our results demonstrate the effectiveness of the double neighborhood strategy in enhancing the performance of Tabu Search, particularly in scenarios where traditional implementations ma

2 - Energy-constrained multi-drone covering tour problem with visit durations

Özge Şatır Akpunar, Şener Akpunar, Tolga Bektas, Cagatay Iris, Grigorios Kasapidis

This study focuses on the deployment of a fleet of drones required to provide temporary communication during emergencies. It is assumed that drones are initially placed at a depot, while the area is divided into subregions that require continuous communication services. In addition, each drone is subject to battery limitations and thus, needs to return to the depot to recharge its battery. As emergency communication is a continuous activity, drones need to visit the subregions in a sequence. The aim here is to provide continuous coverage of the area by utilizing drones and their limited batteries efficiently. The first aspect of interest is how long a drone should hover over a subregion. Hence, it is aimed to keep each drone as much as possible over every visited subregion, to ensure maximum coverage. Decisions include the selection of visited subregions, the optimal hovering time of each drone over the subregions, and the scheduling of the subregion visit sequence, all aimed at maximizing temporal and spatial coverage. The problem is formulated as a mixed-integer linear program (MILP) resembling the covering tour problem. This mathematical model enables us to model the complex interplay between drone movements, area coverage, and battery constraints. Furthermore, a constraint programming (CP) model is proposed to solve the problem and computational experiments are conducted to assess the performance of the CP and MILP models on randomly generated large-scale instances.

3 - Routing in offshore wind farms: A multi-period location and maintenance problem with joint use of a service operation vessel and a safe transfer boat

Majid Eskandarpour, Chandra Irawan, Mohammad Reihaneh, Stefano Starita

This paper studies an interesting logistical problem related to maintaining a set of selected turbines in offshore wind farms. A service operation vessel (SOV), used to support maintenance activities, also carries a safe transfer boat (STB), which is used to transport technicians, parts, and equipment to the turbines. The maintenance activities are optimised over a planning horizon by simultaneously coordinating the SOV and the STB. A mixed-integer linear programming model is designed, where the objective function is to minimise the total maintenance cost. As the proposed mathematical model is hard to solve with a commercial solver, a decomposition approach is developed. A two-stage stochastic programming model is also designed to tackle uncertain conditions, including the duration of maintenance and the STB's travel time. The performance of the solution method is evaluated using the Thanet Offshore Wind Farm, in the southeast of the UK. The results of our experiments show that joint use of an SOV and an STB can yield a lower total maintenance cost than only using an SOV or crew travel vessels (CTVs) that are currently the common practice in maintaining offshore turbines.

4 - Four-echelon facility location supply chain design

Bahram Alidaee, Haibo Wang

At k-level uncapacitated facility location, ensuring each client is served by a sequence of k facilities is common in complex logistical systems, where central depots distribute goods through smaller depots. Due to its complexity, especially when $k > 1$, approximation algorithms are crucial for swiftly obtaining high-quality solutions. This study focuses on a four-echelon supply chain design facility location problem, involving plants (P), ware-houses (W), distribution centers (D), and retail stores (S). The objective is to select locations of plants, retail stores, warehouses and distribution centers to maximize the total profit of serving selected retail stores. We formulate the problem using a bipartite Boolean quadratic programming (BBQP) model. Its solution is obtained through a heuristic approach that employs Tabu search with an r-Opt sequence embedded diversification.

Chair: *Amir Hosseini*

1 - From catch to coast: An optimization approach for vessel routing and scheduling in the Nordic fishing industry

Ali Ghavmaifar, Allan Larsen

The European Union (EU) mandates environmentally friendly, economically viable, and socially sustainable fishing practices for long-term food security, as outlined in the Green Deal objectives. Despite these aims, fisheries still heavily rely on fossil fuels, contributing significantly to global greenhouse gas emissions. Efficient routing can help vessels optimize their fuel consumption by considering the shortest distance to the fishing fields, while effective scheduling can prevent over-fishing of specific areas by avoiding excessive fishing pressure during certain times. Moreover, effective scheduling significantly impacts the quality of fish unloaded at the harbor. Motivated by a real-life case for a company operating in the Nordic fishing industry, we developed a mixed-integer programming model for vessel routing and scheduling considering fuel consumption. The resulting optimization problem is complex featuring various types of uncertainty, with the primary source of uncertainty stemming from the variability of fish population in fishing fields. To tackle this issue, we employ the Sample Average Approximation (SAA) approach. Additionally, a heuristic approach has been devised to efficiently solve large-scale problems. Finally, we examined our proposed approach using real data from the corresponding company. Our results highlight how efficient vessel routing and scheduling in upstream processes of the supply chain can improve overall supply chain efficiency.

2 - An exact solution for the energy constrained AGV scheduling problem

Amir Hosseini, Alena Otto

Automated Guided Vehicles (AGVs) play a pivotal role in modern transportation systems, revolutionizing the movement of goods and materials in warehouses and production systems. Yet, exploiting the performance of AGVs requires careful consideration of their operational constraints during the planning phase. In this study we consider the AGVs scheduling problem, where a fleet of AGVs are used to perform a set of transport requests. The AGVs are energy constrained and their battery needs to be swapped regularly. The problem is to assign transport activities to AGVs, sequence them, and determine optimal battery swap times, such that the makespan is minimized. In essence, this problem can also be viewed as a parallel machine scheduling problem with job-dependent activity cycles and constant maintenance time. For this problem, we introduce a novel mixed-integer linear programming formulation that surpasses existing state-of-the-art models. Then, we develop a logic-based Benders decomposition algorithm embedded in a single search tree framework and strengthened by new sets of lower bounds and valid inequalities. Preliminary computational results indicate the algorithm's capability to solve previously unsolved instances reported in the literature.

3 - Workforce scheduling and routing with substitution skills

Clara Chini Nielsen, David Pisinger

This study addresses the tactical planning aspect of a dynamic technician routing and scheduling problem spanning several days and with home depots. The challenge involves pre-known tasks and dynamically arriving tasks, requiring efficient scheduling to minimize overall

driving distance. Technicians, each possessing specific skills, are dispatched to locations with tasks having time windows and skill requirements. The goal is to minimize driving distance while maximizing task completion. The extended model introduces substitution skills, allowing less qualified technicians to serve tasks with a time penalty. The study presents both an MIP formulation and an ALNS algorithm for optimization. Results, derived from real-life data, are compared against routes executed in an actual company, where technicians can only handle tasks matching their skill sets.

4 - Scheduling on parallel dedicated machines with job rejection

Baruch Mor, Gur Mosheiov

We study scheduling problems on parallel dedicated machines. Thus, each job can be processed on one specific machine only. The option of job-rejection is considered, and the total permitted rejection cost of all the jobs is bounded. Six scheduling problems are solved: (i) minimizing makespan, (ii) minimizing makespan with release-dates, (iii) minimizing total completion time, (iv) minimizing total weighted completion time, (v) minimizing total load, and (vi) minimizing maximum tardiness. Pseudo-polynomial dynamic programming algorithms are introduced for all these NP-hard problems.

On Mathematical Optimization for Explainable and Fair Machine Learning

Stream: Mathematical Optimization for XAI

Invited session

Chair: *Kseniia Kurishchenko*

1 - Making Black-Boxes Explainable and Fair Through Mathematical Optimization

Thomas Halskov, Emilio Carrizosa, Dolores Romero Morales

Machine Learning has increasingly been used for algorithmic decision-making, often through what are considered "black-boxes", i.e., models which do not provide an explanation for their outputs. In this talk, we consider the task of explaining the output and decisions from a given "black-box" to provide an interpretable explanation. Additionally, we tackle fairness concerns that might arise from using "black-box" models, where discrimination can be present. Our approach aims to give a local explanation for an output, while taking into account global fairness and accuracy.

2 - From fair predictions to just decisions

Elif Ersoy, Enis Kayis

Data-driven decisions often raise concerns about fairness and justice, which are frequently confused and used interchangeably. This study investigates the relationship between these two definitions: Fairness is generally considered during the prediction phase of decision-making, yet justice mostly relates to the equality or equity of the resulting decisions. Thus fairness in predictions may not automatically yield just decisions. We propose metrics for quantifying distributive justice in decision-making and investigate how fair predictions relate to just decisions. Two main questions guide our research: Do fair predictions translate into just decisions? Secondly, what is the financial impact of making just decisions? We propose justice metrics and developed mathematical models to improve the quality of the decisions from this viewpoint. We focus on a credit lending application. Our results underscore the distinction between fairness and justice, demonstrating that fair predictions do not guarantee just decisions and may even reduce the overall profit for the lending firm.

3 - Fair treatment allocation via tree ensembles*Kseniia Kurishchenko*

In the treatment allocation problem, a decision maker needs to decide who will receive the treatment. To define the individuals that benefit the most, a machine learning procedure is often used to predict the treatment effect. With these predictions, a model is built to make the allocation decisions. Unfortunately, the data used to build such a model may be discriminating against a group defined by a sensitive attribute such as gender or age. If not carefully trained, the model may provide unfair results, unequally allocating treatment to individuals in the sensitive and non-sensitive groups. In this presentation, I introduce an unfairness measure that can be applied to treatment allocation problems. I propose to measure unfairness as the difference between the average treatment effects in the sensitive group and the non-sensitive group. I introduce a Mathematical Optimization model to have accurate treatment effect predictions and a good level of fairness, which will be the basis for the treatment allocation in forthcoming individuals.

4 - Beyond Efficient Global Optimization: an Algorithm Minimizing Expected Regret*Zizhou Ouyang, Belen Martin Barragan, Xuefei Lu*

Efficient Global Optimization (EGO) has been widely applied to simulation optimization problems, where it uses the Expected Improvement (EI) criterion to navigate the search space for optimal solutions, traditionally relying on Kriging for surrogate modelling and uncertainty estimation. Some existing efforts have attempted to broaden EGO's applicability by substituting Kriging with various machine learning models. However, approximating emulation uncertainty is limited in the absence of Kriging. In this paper, we propose the Expected Regret (ER) criterion, which captures uncertainty through data-driven insights without relying on Gaussian assumptions for uncertainty estimation and enables the direct utilization of machine learning regression models for surrogate modelling. We then apply the proposed algorithm to various simulators of different dimensionalities. Comparative performance evaluations with the classical EGO method demonstrate that our approach achieves competitive results while offering greater flexibility in selecting machine learning models, indicating its potential for addressing high-dimensional optimization problems.

*Invited session*Chair: *Olabode Adewoye*Chair: *Gerhard-Wilhelm Weber*Chair: *Nahid Jafari***1 - Production, pricing and transshipment control on a backlogging manufacturing system***Jianjun Xu*

We study a backlogging inventory model of a manufacturing system with two facilities that periodically produces, transfers and sells a product to stochastic and price-sensitive demands. By expounding an insightful difference in reactive transshipment decisions between lost-sales and backlogging models, we characterize inefficient backorder transshipment around the facilities in the backlogging situations and demonstrate, on account of the inefficient backorder transshipment, that optimal production, pricing, and transshipment decisions can remain complementarity for a group of variables, and behave monotonically. Further, we perform the monotone comparative statics of the complementary variables to establish sensitivities for substitutable demands to optima pricing decisions.

2 - Efficient forecast via transfer learning*Shumin Ma*

Classical Domain Adaptation methods acquire transferability by regularizing the overall distributional discrepancies between features in the source domain (labeled) and features in the target domain (unlabeled). They often do not differentiate whether the domain differences come from the marginals or the dependence structures. In many business and financial applications, the labeling function usually has different sensitivities to the changes in the marginals versus changes in the dependence structures. Measuring the overall distributional differences will not be discriminative enough in acquiring transferability. Without the needed structural resolution, the learned transfer is less optimal. This paper proposes a new domain adaptation approach in which one can measure the differences in the internal dependence structure separately from those in the marginals. By optimizing the relative weights among them, the new regularization strategy greatly relaxes the rigidity of the existing approaches. It allows a learning machine to pay special attention to places where the differences matter the most. Experiments on three real-world datasets show that the improvements are quite notable and robust compared to various benchmark domain adaptation models.

3 - Estimated economic impact of model drift*Andrew Clark*

In the dynamic landscape of data-driven business operations, model drift poses a significant challenge, often leading to substantial economic repercussions. Traditional approaches to quantifying the impact of model drift have been rudimentary, frequently relying on simplistic, ad-hoc calculations. Our paper introduces the Economic Impact Estimation Metric, a pioneering method designed to assign a quantifiable fiat cost to the concept of model drift in a systematic and accessible manner.

4 - Mixed-integer linear optimization for semi-supervised optimal classification trees*Maria Eduarda Pinheiro, Jan Pablo Burgard, Martin Schmidt*

Decision trees are one of the most famous methods for solving classification problems, mainly because of their good interpretability properties. Moreover, due to advances in recent years in mixed-integer optimization, several models have been proposed to formulate the problem of computing optimal classification trees. The goal is, given a set of labeled points, to split the feature space with hyperplanes and assign a class to each partition. In certain scenarios, however, labels are exclusively accessible for a subset of the given points. Additionally, this subset may be non-representative, such as in the case of self-selection in a survey. Semi-supervised decision trees tackle the setting of labeled and unlabeled data and often contribute to enhancing the reliability of the results. Furthermore, undisclosed sources may provide extra information about the size of the classes. We propose a mixed-integer linear optimization model for computing semi-supervised optimal classification trees that cover the setting of labeled and unlabeled data points as well as the overall number of points in each class for a binary classification. Our numerical results show that our approach leads to a better accuracy and a better Matthews correlation coefficient for biased samples compared to other optimal classification trees, even if only few labeled points are available.

1 - Enhancing Last-Mile Delivery Efficiency: A Hybrid Simulation-Optimization Approach for Automated Parcel Locker Network

Javier Faulin, Irene Izco, Adrian Serrano, Luis Cadarso, Bartosz Sawik

The disruptions caused by the COVID-19 pandemic have revealed the necessity for innovative last-mile delivery solutions in urban logistics. Thus, automated parcel lockers offer benefits for courier companies and customers by enhancing flexibility and reducing mileage, delivery time, and emissions. This work introduces a novel approach by integrating a System Dynamics Simulation Model to forecast e-commerce demand in Pamplona, Spain, and assesses its scalability for other cities. Additionally, a bi-objective Facility Location Problem (FLP) is rooted within the simulation environment to test various scenarios of demand coverage. Simulation and demand forecasting are conducted using Anylogic software with the CPLEX optimization solver for the FLP, featuring an ϵ -constraint approach based on economic and demand criteria. Results draw optimal APL networks, derived from the non-dominated solution set of the bi-criteria mathematical programming model through ϵ parameterization. That leads to the identification of the Pareto Frontier and the trade-offs between the number of lockers and parcel demand satisfied. Finally, we encourage the utility of simulation-optimization in addressing dynamic environments.

2 - The value of modular buses optimization

Carlo Filippi, Gianfranco Guastaroba, Lorenzo Peirano, M. Grazia Speranza

Modular bus systems recently attracted attention due to their potential ability increase the flexibility and efficiency in transit networks scheduling. In this work, we focus on the potential advantages of modular buses with respect to fixed-capacity buses. We develop a static optimization model to minimize the total number of modules flowing in a given network of bus lines. The model assumes that for a set of origin-destination pairs located at the stops of the bus network, a rate of transport demand is given and must be satisfied. Buses are formed by one or more connected identical modules. Modules can be attached/detached at the endpoints of a line and at intersections of lines. Empty modules can be transferred among different endpoints and intersections if needed. The model establishes the rate of departure of modules from each endpoint and intersection along each line and the rate of transfer of empty modules among endpoints and intersections that allow to satisfy the demand of transport using a minimum number of modules. By analyzing two extreme cases, we bound the relative value of module sharing among lines and the relative value of empty module rebalancing. Computational experiments on instances derived from real-world transportation networks show the validity of the model and the saving in total transport capacity that can be obtained from a modular system with respect to a fixed-capacity system.

3 - Optimization of auto-carrier routes: a real-world case study in Italy

Andrea Bettinelli, Daniele Feronc

Bertani Trasporti Spa is one of Italy's leading players for logistics services in the automotive sector, delivering more than 5000 vehicles daily. One of the critical tasks in their planning process is the definition of the delivery trips for their fleet of auto-carriers. The problem consists in selecting the best subset of orders that will be served the next day and building a set of optimal routes to deliver them. The routing of the auto-carriers must take into account constraints related to the loading of the vehicles on the carriers. The goal is to use the carriers in the most efficient way (at present there is more demand than transport capacity). This means that we must saturate auto-carriers capacity and create trips visiting few and geographically close delivery points. At the same time we have to minimize the orders not delivered on time. In this work we propose a heuristic method to build optimized routes, based on an Adaptive Large Neighborhood Search (ALNS) scheme, where loading constraints combine explicit rules with coefficients dynamically learned from historical data and feedback from expert planners.

4 - Feasibility Prediction in Attended Home Delivery with Uncertainty: A Machine Learning Approach

Liana van der Hagen, Niels Agatz, Remy Spliet

In attended home delivery, retailers usually let customers select a delivery time slot for receiving their orders. The delivery capacity, i.e., the number of vehicles and drivers, is often fixed and inflexible in the short term. To effectively use their delivery capacity, e-grocers may dynamically close time slots for certain new customers given the already accepted customer orders. One complicating factor is that for example online grocers allow customers to change their order basket at any time before the cut-off. Consequently, the e-grocer is uncertain about how much vehicle capacity should be reserved for each of the customers during the booking process. We study the challenges that arise with this order size uncertainty and propose strategies to deal with it. For each of the time slots to be evaluated, we use machine learning to quickly predict the probability that a feasible route plan exists that visits all accepted customers in their selected time slot.

Invited session

Chair: Julio González-Díaz

1 - Solving MINLPs to Global Optimality with FICO Xpress Solver

Tristan Gally

This talk introduces the global optimization capability within FICO Xpress Solver, which allows to solve general mixed-integer nonlinear problems to global optimality. We will discuss how existing features of the MILP and local NLP solvers are used and explain several different extensions for, e.g., spatial branching and convexification cuts, and their performance implications.

2 - Global optimization of continuous and discrete nonlinear programs with BARON

Yi Zhang, Nikolaos Sahinidis

BARON, under development since the early 1990s, has evolved into a robust computational system for solving continuous and discrete optimization problems to global optimality. The current generation of BARON focuses on enhancements in hybrid relaxations, presolve methods, convexification techniques, heuristics, and robustness improvements. Our experiments underscore the importance of all algorithmic components within the branch-and-reduce framework. Computational comparisons against state-of-the-art global and local solvers highlight BARON's superior performance.

3 - Global MINLP in Gurobi

Tobias Achterberg

With Gurobi 9.0 we introduced an API to define univariate nonlinear convex and nonconvex constraints, which Gurobi would then automatically approximate using piece-wise linear functions. With Gurobi 11.0, the user can now choose to solve models with nonlinear constraints directly in order to get a globally optimal solution to the mixed integer nonlinear program (MINLP) at hand.

In this talk, we review the algorithmic technology employed in Gurobi 11 to address nonlinear constraints. We highlight the strengths and limitations of our approach and give an outlook on further developments that will be part of Gurobi 12.

4 - RAPOSa: A free global solver for mixed integer polynomial optimization problems

Julio González-Díaz, Brais González Rodríguez, Iria Rodríguez-Acevedo, Ignacio Gómez-Casares

This talk aims to showcase the latest developments in RAPOSa, a global solver for polynomial optimization problems, with a primary focus on its extension to address mixed-integer problems. The talk will delve into various facets of the key challenges encountered in this extension, along with some numerical experiments designed to assess the performance of different approaches, both relative to one another and also relative to other state-of-the-art global solvers for MINLP problems.

Regarding the extension to mixed integer problems, we will discuss approaches targeted to improve the quality of the final bounds returned by the algorithm. In particular, for the upper bounds we will discuss the integration of the calls to auxiliary local solvers (discrete and continuous) and the trade-offs that arise when trying to do it efficiently.

1 - Dealing with noisy labels in text analytics: an application in crime analytics for prioritizing reports

Carla Vairetti, Sebastian Maldonado, Richard Weber

Deep learning has emerged as the predominant method for text analytics owing to its capacity to learn language patterns from vast datasets and subsequently apply this knowledge to specific tasks. In this study, we leverage deep learning techniques to enhance the categorization of public security reports submitted by ordinary individuals through a mobile application in Chile. Users select a category to report an incident from a wide array of options, encompassing everything from lost pets and disturbing noises to accidents involving injuries or burglary. They also have the option to provide a description of the incident. A primary challenge arises from users often misreporting events in the first category presented in the app. While the app has proven invaluable for municipalities and police departments in efficiently deploying resources and patrols to address incidents and prevent crime, its prioritization scheme relies on the category provided by the user. This study introduces a machine learning solution employing BERT and other Transformer architectures to learn from incident descriptions and accurately assign labels, thereby improving event prioritization. Our results show a positive predictive performance. Additionally, the model shows potential to extract further insights from descriptions, augmenting prioritization by, for instance, assessing the severity of accidents or crimes.

2 - Using crime report app data to predict burglary via machine learning

Sebastian Maldonado, Joaquín Roa, Carla Vairetti, Richard Weber

Predictive policing represents a productive avenue of research utilizing analytics to anticipate potential criminal activities. This study aims to develop a learning machine capable of forecasting the occurrence of specific crime types in a given area based on historical data. The primary objective of this model is to furnish municipalities and police departments with a tool to deploy patrols and allocate resources efficiently. Data was collected from a Chilean crime report app, encompassing various criminal events and suspicious activities reported by the public. Under the assumption that past reports serve as reliable predictors of future criminal activities, we formulate a classification

problem to forecast burglary and motor vehicle theft in a designated area. Promising outcomes were achieved using conventional statistical and machine learning methods such as logistic regression, decision trees, and gradient boosting, attaining a balanced accuracy exceeding 80%. We also discuss the use of graph-based deep learning and other network architectures to take advantage of the spatial structure of the problem.

3 - A Systematic Review and Experimental Evaluation of Social Network Analytics for Anti-Money Laundering

Bruno Deprez, Toon Vanderschueren, Wouter Verbeke, Bart Baesens, Tim Verdonck

Money laundering presents a pervasive global challenge, placing a burden on society through the financing of illegal activities. To combat this phenomenon, the inclusion of network information in the modelling pipeline is increasingly being explored for more effective detection, exploiting the fact that money laundering necessarily interconnected parties. This evolution has resulted in a strong growth of the literature on social network analytics (SNA) for anti-money laundering (AML) in the past few years. At the same time, the increasing attention for network approaches for AML in the literature has created important challenges for researchers and practitioners. There is no clear overview of the existing work, there exist limited insights into how different methods compare, and it is not clear which approach works best in practice. The main objective of this paper is to construct a taxonomy of SNA for AML using a systematic literature review. This review is supplemented by an extensive experimental evaluation of graph learning methods, going from manual feature engineering, over shallow representation learning to graph neural networks. These are evaluated on two money laundering datasets, a crypto-currency and a proprietary transaction data set. The results highlight the strengths and weaknesses of the different graph learning methods in the specific context of money laundering.

4 - Optimization in Social Networks to Identify Related Crimes

Richard Weber, Carla Vairetti, Fredy Troncoso, Sebastian Maldonado, Alex Barrales-Araneda, Valentina Reyes, Pablo Pincheira

We introduce an innovative methodology for social network analysis that clusters similar criminal activities without initially identifying the perpetrators involved. This approach leverages an optimization model to facilitate the optimal grouping of past crimes, utilizing a newly developed similarity measure. Drawing from existing models where a delinquent is represented as a node and a mutual crime as a connecting link, we propose an "inverted social network" framework. In this novel network, each node symbolizes a crime event, and a link between two nodes signifies a similarity exceeding a predetermined threshold. This methodology employs a recently introduced similarity measure, specifically designed to encapsulate the unique characteristics inherent to this application domain. An optimization model is utilized to aggregate crimes based on their similarity, showcasing the method's applicability across various instances where the involved criminals are yet to be identified. This technique proves invaluable for deciphering patterns within crime databases and serves as an investigative tool for examining recent crimes with minimal information on the culprits. We will present the most recent findings from applying this methodology in collaboration with the Chilean Prosecutor's Office, illustrating its potential and outlining avenues for future exploration.

1 - Don't be so Monotone: Relaxing Stochastic Line Search in Over-Parameterized Models

Leonardo Galli

Recent works have shown that line search methods can speed up Stochastic Gradient Descent (SGD) and Adam in modern over-parameterized settings. However, existing line searches may take steps that are smaller than necessary since they require a monotone decrease of the (mini-)batch objective function. We explore nonmonotone line search methods to relax this condition and possibly accept larger step sizes. Despite the lack of a monotonic decrease, we prove the same fast rates of convergence as in the monotone case. Our experiments show that nonmonotone methods improve the speed of convergence and generalization properties of SGD/Adam even beyond the previous monotone line searches. We propose a POLYak NONmonotone Stochastic (PoNoS) method, obtained by combining a nonmonotone line search with a Polyak initial step size. Furthermore, we develop a new resetting technique that in the majority of the iterations reduces the amount of backtracks to zero while still maintaining a large initial step size. To the best of our knowledge, a first runtime comparison shows that the epoch-wise advantage of line-search-based methods gets reflected in the overall computational time.

2 - A globally convergent gradient method with momentum

Matteo Lapucci, Giampaolo Liuzzi, Stefano Lucidi

Among many effective strategies to speed up first-order solvers for smooth nonlinear optimization problems, Polyak's momentum (or Heavy-Ball) certainly stands out. The idea of Polyak consists of exploiting information about past iterates, carrying out a step along a direction which is a linear combination of a suitable gradient-related descent direction and the previous step. The idea of this update rule is that, partly following the direction of last iteration, oscillations can be controlled and acceleration can be obtained in low curvature regions. However, except for the quadratic case, the selection of the two parameters defining the update is not trivial; to this aim, we develop an approach where these coefficients are simultaneously determined by a simple inexact bidimensional search. This strategy allows us to define a class of gradient methods with momentum enjoying, under reasonably weak assumptions, global convergence guarantees and an optimal worst-case complexity bound in the nonconvex setting. To the best of our knowledge, these results are novel to the literature. Moreover, extensive computational experiments show that the gradient methods with momentum here presented outperform conjugate gradient methods and are (at least) competitive with the state-of-art method for unconstrained optimization, i.e., L-BFGS method.

3 - Stochastic gradient descent with momentum and line-searches

Davide Pucci, Matteo Lapucci

In recent years, the adoption of line-search techniques within incremental gradient-based methods for finite-sums problems has gathered considerable interest among researchers. These techniques enable the use of substantially larger step-sizes while maintaining robust convergence properties and empirically showing a reduction in the number of iterations required to achieve high-quality solutions. Most recent research focused on incorporating line-searches within Stochastic Gradient Descent (SGD), as the usage of a descent direction for the mini-batch objective is essential to ensure the line-search terminates in a finite number of steps.

In this talk we discuss the nontrivial integration of these line-search techniques within algorithmic frameworks employing Polyak's momentum terms. In particular, we are interested in structured ways to combine stochastic gradients and momentum to obtain a suitable search direction together with a proper initial step-size for the line search. We then present a computational comparison, carried out on both convex and nonconvex test problems, concerning different viable options to achieve this goal. We thus offer insights into the potential strengths and drawbacks of the considered approaches, with respect to other state-of-the-art methods.

4 - A Block Cubic Newton method with Greedy Rule

Andrea Cristofari

In this talk, a Block Cubic Newton method is proposed for the unconstrained minimization of a non-convex function with Lipschitz continuous Hessian matrix. At each iteration, the proposed method first selects a block of variables by means of a greedy rule, that is, on the basis of the optimality violation. Then, the next point is obtained by computing an approximate minimizer of the cubic Newton model. Global convergence to stationary points is proved and complexity results are given. Finally, some numerical results on optimization problems from machine learning are presented.

1 - Perpetual American Options in Two-Dimensional Diffusion Models

Pavel Gapeev

We study the perpetual American options optimal stopping problem in two-dimensional diffusion models with linear and multiplicative payoff structure. It is assumed that the risky asset prices are modelled as geometric Brownian motions driven by constantly correlated standard Brownian motions. We find closed formulas for the value functions expressed in terms of the optimal stopping boundaries which in turn are shown to be unique solutions to nonlinear Fredholm integral equations. A key argument in the existence proof is played by pointwise maximisations of the expression obtained by the change-of-measure arguments. These provide tight bounds on the optimal stopping boundaries as well as describes its shape and asymptotic behaviour for small or large coordinate values of the risky asset prices. This is a joint work with Goran Peskir (Manchester).

2 - Singular Control in Inventory Management with Smooth Ambiguity

Arnon Archankul, Jacco Thijssen

We consider singular control in inventory management under Knightian uncertainty, where decision-makers have a smooth ambiguity preference over Gaussian-generated priors. We demonstrate that continuous-time smooth ambiguity is the infinitesimal limit of Kalman-Bucy filtering with recursive robust utility, heuristically proposed by Hansen and Sargent (Journal of Economic Theory, 146(3):1195-1223, 2011). Additionally, we prove that the cost function can be determined by solving forward-backward stochastic differential equations with quadratic growth. Using variational inequalities in a viscosity sense, we derive the value function and optimal control policy. By a coordinated transformation, we simplify the problem into two-dimensional singular control, offering insights into model learning and aligning with classical singular control free boundary problems. This study marks the first attempt, to our knowledge, to integrate singular control with smooth ambiguity.

3 - Investment under Uncertainty: Abrupt Business Environment Changes and Time-to-Build

Nathan Bun, Kuno Huisman, Peter Kort

Recent geopolitical factors have a considerable effect on the economic environment of firms. We study abrupt business environment changes that affect demand growth and demand uncertainty in combination with time-to-build in a dynamic investment model of the firm. The business environment can either be a regime of relative prosperity or a regime of geopolitical turmoil. The firm has to decide on the timing and size of the investment. We find that time-to-build by itself does not affect the size and only delays the investment resulting in a constant project

value at the moment of the investment. Time-to-build also does not affect the size greatly if regime shifts are included. The effect of the shift rates on the investment decision is twofold. The firm prioritizes the current regime in the investment decision if the probabilities of regime shifts occurring are small. If the probabilities of regime shifts occurring are large, the firm invests based on the weighted average of the two regimes.

4 - Optimal entry deterrence under uncertainty

Peter Kort, Richard Hartl, Stefan Wrzaczek

The objective of this paper is to study an incumbent-entrant model under uncertainty. The entrant knows the realization of the random variable(s) before it makes its decision on entry and eventual capacity choice. So all the uncertainty is on the incumbent's side. The sources of uncertainty consider the characteristics of the entrant's product and the entry cost the entrant needs to incur before becoming active. We know from the literature that the incumbent-entrant setup could result in three different outcomes: blockaded entry, i.e., the incumbent behave like a monopolist and the entrant does not enter, deterred entry, i.e., the incumbent overinvests to make the market unprofitable for the entrant, and accommodated entry. The main result from our work is that under uncertainty there can be four outcomes: apart from blockaded entry and accommodated entry, it can be either 100% entry deterrence or entry deterrence with a certain probability.

1 - A Nested Primal-Dual Iterated Tikhonov Method for Regularized Convex Optimization

Stefano Aleotti, Silvia Bonettini, Marco Donatelli, Marco Prato, Simone Rebegoldi

Proximal-gradient methods are iterative first-order techniques that prove useful in various applications, such as image deblurring and denoising. Alongside the potential issue of slow convergence, one crucial challenge is the assumption that the proximal operator is computable in closed form. To tackle this, adopting a variable metric approach and integrating an extrapolation step can enhance the efficiency of these methods. However, a significant concern arises from the inexact computation of the proximal operator, often addressed through a nested primal-dual solver.

In this work, we introduce a nested primal-dual method designed for efficiently solving regularized convex optimization problems. Our proposed method approximates a variable metric proximal-gradient step with extrapolation by executing a predetermined number of primal-dual iterates while adjusting the step length parameter through an appropriate backtracking procedure.

Furthermore, we investigate the numerical performance of our proposed method on an image deblurring problem, defining a scaling matrix inspired by the Iterated Tikhonov method. The numerical results demonstrate that the combination of such scaling matrices and Nesterov-like extrapolation parameters yields an effective acceleration towards the solution of the initial problem.

2 - Parameter-free FISTA

Luca Calatroni, Jean-François Aujol, Charles Dossal, Hippolyte Labarrière, Aude Rondepierre

We propose an adaptive backtracking and restarting strategy to automate a variant of the Fast Iterative Soft-Thresholding Algorithm (FISTA) for structured optimization problems. Under a generalized (non-restrictive) strong convexity growth condition, we prove the linear convergence of function values generated by the resulting parameter-free algorithm. The algorithm's performance and versatility are demonstrated on exemplar imaging problems.

3 - Solving large-scale nonlinear least-squares with random Gauss-Newton models

Benedetta Morini, Stefania Bellavia, Greta Malaspina

We address the solution of large-scale nonlinear least-squares problems by stochastic Gauss-Newton methods combined with a line-search strategy. The algorithms proposed have per-iteration computational complexity lower than classical deterministic methods, due to the employment of random models inspired by randomized linear algebra tools. Under suitable assumptions, the stochastic optimization procedures can achieve a desired level of accuracy in the first-order optimality condition. We discuss the construction of the random models and the iteration complexity results to drive the gradient below a prescribed accuracy, then we present results from our computational experience.

4 - Mean square convergence analysis of nonlinear distributed recursive estimation under heavy-tailed noise

Manojlo Vukovic, Dusan Jakovetic, Dragana Bajovic, Soumya Kar

Distributed recursive estimation under heavy-tailed sensing and communication noises is considered. Therein, the sensing and communication noises can be mutually correlated while independent identically distributed over iterations. A general setting is assumed where both the sensing and communication noises may have infinite variances. A consensus+innovations distributed estimator is presented, involving a general nonlinearity in both consensus and innovations update rules. We present several results on the estimator performance. It is shown that the mean squared error (MSE) of the estimation converges to zero, and moreover, an explicit MSE sublinear convergence rate is established. In addition, almost sure convergence and asymptotic normality results are derived. Analytical and numerical examples confirm that the presented method converges under the simultaneous heavy-tail communication and sensing noises, in contrast with existing estimators that break down under the same setting.

Stochastic Optimization for Energy Transition

Stream: Stochastic, Robust and Distributionally Robust Optimization

Invited session

Chair: Patrizia Beraldi

1 - ML-Driven Day-ahead Offering for RES Generators in Uncertain Balancing Markets

Wenxiu Feng, Carlos Ruiz

We examine a renewable energy source (RES) generator engaged in short-term electricity market trading. Traditionally, variable RES generation has been exempted from balancing responsibilities; however, this exemption is no longer prevalent in many markets due to increasing penetration. We consider a generator participating in both a day-ahead market and a subsequent balancing market. We seek the RES

generator's optimal day-ahead offerings in terms of energy volumes, considering the impact of balancing market settlements. To this end, we implement and analyze the accuracy of state-of-the-art Machine Learning (ML) models in forecasting imbalance signs, prices, and other market outcomes, assessing the potential to enhance RES's profitability. Additionally, we evaluate the impact of employing storage techniques to mitigate the intermittency associated with RES capacity. We develop a two-stage stochastic optimization model. The first stage involves day-ahead decisions that anticipate scenario-dependent balancing settlements and real-time battery operation in the second stage. The model uses improved forecasting scenarios generated by an ensemble of ML models, considering contextual and past historical market outcomes. We conduct an extensive set of out-of-sample simulations using real data from the Spanish market, and under the two main financial settlement mechanisms available for balancing markets: single and dual pricing, each with distinct implications for the RES generator.

2 - Stochastic optimization for unit commitment applied to the security of supply

Jonathan Dumas

Transmission system operators employ reserves to deal with unexpected variations of demand and generation to guarantee the security of supply. The French transmission system operator dynamically sizes the required margins using a probabilistic approach relying on continuous forecasts of the main drivers of the uncertainties of the system imbalance and a 1 % risk threshold. However, it does not consider the cost of units and the lost load. In addition, it does not provide insight into which means to activate upward/downward and when to face a deficit of margins.

This work presents a unit commitment strategy using stochastic optimization, including i) the fixed and variable costs of power plants and the costs of lost load and spillage and ii) uncertainties of the renewable generation, consumption, and technical failures of units.

A multi-stage stochastic program formulates this problem and is approximated with a rolling sequence of two-stage stochastic programs. A simplified version that solves a single two-stage stochastic program is implemented on a case study comprising a few nuclear and fossil-based units due to tractability issues related to the technical constraints of units. Extensions are required to: Better model the uncertainties. Consider other risk-aversion approaches, such as using a CVaR or chance-constrained. Deal with the tractability issues. Model the lost load cost according to the volume of not-served energy and outage duration.

3 - A robust optimization approach for the strategic design of EV charging stations

Giovanna Miglionico, Patrizia Beraldi, Giovanni Giallombardo

Although the environmental policies have pushed for the introduction of electric vehicles (EVs), the development of the EV industry is slowed down by the issues related to short driving range and extended recharging time. These challenges underscore the need for increased investment in the charging infrastructure. We consider strategic and operational planning decisions arising in managing plug-in electric vehicle (PEV) charging stations. At a strategic level, the station owner, makes decisions on the capacity of the station infrastructures (PEV-charging piles, renewable generators, and energy storages) and on the retail prices for PEV-charging energy. These decisions depend on the unknown values for the productivity of the renewable resources, for the number of PEV clients and for the wholesale prices. Based on the worst possible outcome for these scenarios the PEV owner would like to make the best operational decisions regarding the quantity of supplementary energy to be produced. We introduce a robust formulation of the problem and solve it by an iterative method designed for solving linearly constrained optimization problems, whose non-smooth non-convex objective function is defined as the pointwise maximum of finitely many concave functions. We provide some computational results to compare the adopted solution method with those derived from the literature.

4 - Optimizing System Sizing: A Stochastic Bi-Level Approach for Green Electricity Retailers

Patrizia Beraldi

We present a stochastic Bi-Level approach to support electricity retailers in making investment decisions in sustainable energy systems to supply green electricity. The interaction between the retailer, acting as leader, and the follower, representing a set of residential prosumers, is modelled as a Stackelberg game. Both players solve an optimization problem subject to uncertainty related to fluctuating market prices, weather variables and prosumer load. In particular, the leader solves a strategic problem referring to the optimal sizing of the energy system while conjecturing the possible reaction of the follower to the offered tariffs. The follower reacts to the communicated prices defining the procurement plan in terms of amount of electricity to purchase from the retailer and competitors so to minimize the expected electricity bill. The follower's reaction affects the retailer's profit computed as difference between the revenue from electricity selling and the total cost. To account for the retailer's attitude towards risk, the upper level problem includes a safety measure to control the average profit that can be gained in a given percentage of unfavourable situations. A tailored solution approach is developed and tested on a realistic case study calibrated on the Italian electricity market. Numerical results demonstrate the efficiency of the proposed approach and validate the significance of explicitly dealing with uncertainty and integrating safety measures.

1 - Water quality management based on proportionality in multi-issue problems with crossed claims

Rick Acosta, Encarnación Algaba, Joaquín Sánchez-Soriano

Water pollutants can be classified into three categories, each of which includes several classifications of substances. In this paper, we present a methodology based on bankruptcy models to determine the emission limits of polluting substances belonging to more than one category. We model the problem as a multi-issue allocation problem with crossed claims and introduce the constrained proportional awards rule to obtain the emission limits. This rule is based on the concept of proportionality and extends the proportional rule for bankruptcy problems. We also provide an axiomatic characterization of this rule. Moreover, this allocation rule is illustrated by means of a numerical example based on real-world data. Finally, managerial and policy implications of this approach for water pollution control are given.

2 - Bankruptcy Problems over Time

Maaïke Vollebergh, Wout Dullaert, Arantza Estévez Fernández, Yousef Ghiami

A bankruptcy problem occurs when several agents each claim a portion of an estate that is insufficient to satisfy all the claims, raising the question of how to divide the estate equitably among the agents. In the traditional bankruptcy problem, there is a single decision made at a single point in time. Looking at the applications of bankruptcy, e.g. water sharing or vaccine allocation, one can see that these are actually problems where allocations have to be made over time. In this presentation, we introduce the concept of bankruptcy over time in the Multi-period Bankruptcy Problem. We also present three different perspectives on bankruptcy over time. For each of these perspectives, we present mechanisms to generalize existing bankruptcy rules to the multi-period setting. Moreover, we formulate properties of these multi-period bankruptcy rules, and prove that these properties are inherited from the traditional bankruptcy rules. Finally, we present

efficient algorithms to apply the bankruptcy rules using recursive methods. By introducing the Multi-period Bankruptcy Problem, presenting and computing multi-period bankruptcy rules, we want to extend the usefulness of bankruptcy rules in practice and open avenues for further research on multi-period bankruptcy problems.

3 - Revenue distribution in streaming platforms

Juan Carlos Gonçalves-Dosantos, Ricardo Martinez, Joaquin Sánchez-Soriano

The streaming industry has experienced exponential growth over the past decade. Streaming platforms provide subscribers with unlimited access to a diverse range of services, including movies, TV shows, and music, in exchange for a subscription fee. We take an axiomatic approach to the problem of how to share the overall revenue obtained from subscription sales among services or content producers. In doing so, we provide normative justifications for several distribution rules.

4 - Revenue sharing at music streaming platforms

Gustavo Bergantinos, Juan D. Moreno-Ternero

We study the problem of sharing the revenues raised from subscriptions to music streaming platforms among content providers. We provide direct, axiomatic and game-theoretical foundations for two focal (and somewhat polar) methods widely used in practice: pro-rata and user-centric. The former rewards artists proportionally to their number of total streams. With the latter, each user's subscription fee is proportionally divided among the artists streamed by that user. We also provide foundations for a family of methods offering a compromise among the previous two, which addresses the rising concern in the music industry to explore new streaming models that better align the interests of artists, fans and streaming services.

1 - The size of the handicap

Marianna E.-Nagy, Tibor Illés, Laszlo Vegh

The handicap is a matrix parameter associated with the linear complementarity problem (LCP). While LCP is an NP-hard problem, there are special cases, such as when the handicap of its coefficient matrix is finite, where an interior point algorithm can efficiently solve the problem. However, the theoretical complexity of the algorithm is linearly dependent on the handicap. Consequently, a key and relevant inquiry is to give an upper bound on the size of the handicap. We show that, with a fixed matrix dimension, the handicap cannot be arbitrarily large. more precisely, we prove the conjecture that it cannot be double exponential in the bit size of the matrix.

2 - Ai-Zhang-type interior-point algorithms for solving linear complementarity problems

Anita Varga, Marianna E.-Nagy

This talk investigates a long-step interior-point framework for solving linear complementarity problems. The algorithmic framework combines the approach of Ai and Zhang and the algebraically equivalent transformation technique proposed by Darvay. We investigate a set of sufficient conditions on the transformation function applied in the algebraically equivalent transformation technique, under which the general algorithmic framework's convergence and best known iteration complexity can be proved. We analyze the theoretical and practical role of different neighborhood definitions. As expected, the proposed conditions depend on the definition of the neighborhood of the central path.

3 - A predictor-corrector algorithm for semidefinite programming that uses the factor width cone

Etienne De Klerk

We propose an interior point method (IPM) for solving semidefinite programming problems (SDPs). The standard interior point algorithms used to solve SDPs work in the space of positive semidefinite matrices. Contrary to that the proposed algorithm works in the cone of matrices of constant factor width. We prove global convergence and provide a complexity analysis. Our work is inspired by a series of papers by Ahmadi, Dash, Majumdar and Hall, and builds upon a recent preprint by Roig-Solvas and Sznajder [arXiv:2202.12374, 2022]. This talk is based on joint work with Felix Kirschner.

4 - Simplified Analysis of Kernel-Based Interior-Point Methods for $\mathbb{P}_*(\kappa)$ -Linear Complementarity Problems

Goran Lesaja, Zsolt Darvay, Marianna E.-Nagy, Petra Renáta Rigó, Anita Varga

We consider kernel based Interior-point methods (IPMs) for $\mathbb{P}_*(\kappa)$ -Linear Complementarity Problems (LCP) that are based on the class of Eligible kernel functions (EKFs). The importance of kernel-based IPMs stems from the fact that the iteration bounds of large-step IPMs is significantly improved for some instances of EKFs. However, the derivation of the iteration bounds for particular EKFs is usually long and quite involved which was the motivation to investigate whether this process can be simplified and under what conditions.

Hence, we introduce additional conditions on the class of EKFs, which are not very restrictive, however, they allow for the significant simplification of the analysis and calculation of iteration bounds. We derive a new simplified scheme to calculate iteration bounds and illustrate it with calculation of iteration bounds of most EKFs with polynomial and exponential barrier terms mentioned in the literature. In all cases we match the complexity obtained using the classical scheme.

Advances in Stochastic Modelling and Applied Probability I

Stream: Advances in Stochastic Modelling and Learning Methods

Invited session

Chair: *Ioannis Dimitriou*

Chair: *Tuan Phung-Duc*

1 - A discrete choice model for multi-product pricing based on the Markov Chain Choice Model combined with reservation prices

Ivo Adan, Laura Sprenkels, Zumbul Atan

A customer choice model, based on the Markov Chain Choice Model with reservation prices, is proposed to solve the problem of finding optimal selling prices for substitutable products. The model includes both customers' willingness to pay and substitution behavior explicitly, and can handle any type of correlation between products. A discrete version of the model is formulated and solved to optimality. This discrete model is instrumental in a simulation procedure to estimate optimal reservation prices in the original continuous model.

2 - Call center data analysis and model validation

Ger Koole, Siqiao Li, Sihan Ding

We analyze call center data on properties such as agent heterogeneity, customer patience and breaks. Then we compare simulation models that are different in the ways these properties are modeled. We classify them according to the extent in which they approach the actual service level and average waiting times. We obtain a theoretical understanding on how to distinguish between the model error and other aspects such as random noise. We conclude that modeling explicitly breaks and agent heterogeneity is crucial for obtaining a precise model.

3 - Analysis of Waiting Times in a Novel Two-Class Queueing Model Motivated by Road Traffic

Joris Walraevens, Sara Sasaninejad, Sabine Wittevrongel

Multiple vehicle types typically use the same roads simultaneously. These different types do not only differ in attainable speeds but also in feasible accelerations and decelerations. For instance, freight vehicles accelerate at a slower pace than normal vehicles leading to slower queue dissipation at for instance intersections and creating gaps in these queues. In this paper, we propose a novel discrete-time FCFS queueing model with two types of traffic (freight and regular vehicles for instance) where service times depend on whether freight vehicles are present or not at the start of these service times. We analyze the delay of individual vehicles of both types and characterize gap lengths created by different accelerations of different vehicle types.

4 - On dual risk models with dependence structure

Ioannis Dimitriou

In this work we consider generalizations of the dual risk model with proportional gains, constant expense rate, and innovations that arise according to a renewal process. Among others, we consider the case where the proportional parameter can be a constant or a random variable, as well as cases where several independence assumptions among gain/innovation sizes and the interarrival times of the gains/innovations are lifted. More precisely, we consider the case with causal dependence structure, as well as the case where the dependence is based on the generalized Farlie-Gumbel-Morgenstern copula. We also consider the case where the proportional parameter is randomly chosen, as well as the case where we may have two-sided jumps. The ruin probability and the distribution of the time to ruin are determined.

Vector and Set Optimization II

Stream: Vector and Set Optimization

Invited session

Chair: [Elena Molho](#)

1 - Existence and uniqueness of solutions to the Bellman equation in stochastic dynamic programming

Juan Pablo Rincon-Zapatero

We obtain new results about the existence and uniqueness of solutions to the Bellman equation of stationary stochastic dynamic optimization problems in discrete time and infinite horizon. We extend previous results for weighted and local contractions, through a generalization of the notion of Banach contraction which is especially well suited for problem where the shock variables are exogenous and/or the discount factor may depend on uncertain events. We apply the results obtained to an endogenous growth model and compare our approach with other well known methods, such as the weighted contraction method, countable local contractions and the Q-transform.

2 - On optimality conditions for nonsmooth multiobjective programming problems with vanishing constraints

Tadeusz Antczak

A particular form of extremum problems which attracted the attention of the optimization community over more than the past decade are a so-called optimization problem with vanishing constraints. This follows from the fact that optimization problems of such a type have been served as a model for many extremum problems from structural and topology optimization. In most of works in the optimization literature, optimality and duality results have been proved only for differentiable scalar optimization problems with vanishing constraints. In our considerations, we shall investigate optimality results for a new class of nondifferentiable multiobjective programming problems with vanishing constraints. Namely, we derive both necessary and sufficient optimality conditions for a new class of such nonsmooth vector optimization problems.

3 - Robust games with vector payoffs

Elisa Caprari, Lorenzo Cerboni Baiardi, Elena Molho

In non-cooperative game theory, it may happen that players' payoffs are represented by vector parametric functions, with no information available on the probability distribution of the parameters. A fruitful approach to this problem is to consider all the realizations of the parameters in a set-valued payoff. The worst case scenarios can be considered by the introduction of an appropriate quasi-order relation between sets. We address the question whether scalarization and robustification can be commuted in a non componentwise framework.

4 - Games with incomplete preferences: a pointwise completion approach

Elena Molho, Elisa Caprari, Lorenzo Cerboni Baiardi

We introduce a pointwise axiomatic approach to completion of incomplete preference relations through appropriate value functions. We consider an abstract scalarization framework, originally developed in the field of vector optimization, in order to tackle generic partial quasi orders. We apply this approach to study non cooperative games where players have incomplete preferences. In this context, our results allow us to obtain both necessary and sufficient Nash equilibrium conditions. We compare our representation results with other approaches to preference completion, in the special case where value functions are Aumann utilities. In detail, we identify minimal sets of Aumann utilities that allow us to find all Nash equilibria of a game with incomplete preferences, with no need of additional assumptions. As a special case, we reframe our pointwise approach in vector games, where players have vector-valued payoffs and partial orders on players' outcomes naturally arise. We characterize Nash equilibria in vector games by scalarization, extending to the non convex case the results originally developed by Shapley (1959).

Decomposition methods for Quantum Optimization

Stream: Quantum Computing Optimization

Invited session

Chair: [Philippe Lacomme](#)

1 - SAT resolution with an Indirect Quantum based approach

Philippe Lacomme, Gérard Fleury

In recent years, there has been a significant increase in the adoption of Boolean Satisfiability (SAT) models and algorithms to tackle various challenges in Engineering and Computer Science. This surge can

be credited to the notable advancements in SAT algorithms during this period, allowing for the resolution of more complex problem instances across diverse application domains.

We present a highly specific modelization of SAT, with a resolution approach based on Quantum Approximate Optimization Algorithm (QAOA). This particular methodology enables the solution of SAT problems with 96 clauses, currently representing the largest problem sizes solvable using quantum approaches.

2 - A quantum search algorithm exploiting specific time windows structure. Application to production units planning problems.

Rodolphe Griset

Quantum search, spurred by Grover's algorithm in 1996, has long held promise in quantum computing for its quadratic speedup over classical algorithms in unsorted set searches. However, demonstrating a quantum advantage on finding the best solution to a combinatorial problems is not straightforward due to the existence of efficient classical heuristics, insufficient speedup and inherent quantum noise. In this study, we investigate a novel approach: constructing a superposition of states of reduced size by leveraging problem structure before employing quantum search algorithms. We apply this methodology to a multi-machine job scheduling problem characterized by specific time window structures, local job constraints within machines, and resource limitations. Our objective is to minimize costs associated with job dates, aiming to identify solutions below a predefined threshold. This model is particularly suited for multi-year planning in power plant maintenance, where machines represent production units and jobs signify maintenance outages for specific units. We exploit the unique structure of spacing constraints between jobs and structured time windows to create a superposition of state subspaces. Subsequently, we apply amplitude amplification by designing two oracles to account for resource constraints and the cost function. This innovative approach holds promise for improving the efficiency and effectiveness of quantum optimization techniques in real-world applications.

3 - Efficient Encoding for the Traveling Salesman Problem using Quantum Variational Algorithm

Inran Meghazi, Eric Bourreau

The Traveling Salesman Problem (TSP) stands as a quintessential challenge in combinatorial optimization, with vast implications across industries. Given the absence of efficient classical algorithms to solve this problem, there's a great interest in quantum computing to address such challenge. However, the current quantum computing landscape is dominated by Noisy Intermediate Scale Quantum (NISQ) computers. Hence, the development of efficient encodings becomes paramount in harnessing the potential of these computers to tackle complex problems like the TSP. While previous encoding techniques have been introduced, they lacked the essential characteristic of proximity between neighboring solutions. We propose an algorithm capable of efficiently computing an encoding with proximity. Through experimentation, we show that our encoding facilitates superior performance of variational quantum algorithms compared to existing encodings. Furthermore, our approach requires fewer gates and qubits compared to conventional algorithms such as QAOA, highlighting its potential for practical quantum computing implementations.

4 - Solving Combinatorial Optimization Problems with Quantum Annealers

Janez Povh

In this talk, we present a comprehensive analysis of solving two famous NP-hard problems: the Max-Cut and the Stable Set Problem. While the former is equivalent to Quadratic Unconstrained Binary Optimization (QUBO) problem, the latter needs to be reframed as a QUBO problem. We solve both using exact solvers like GUROBI or BigBin, and approximately by quantum annealing solvers such as the D-Wave quantum processing unit and D-Wave hybrid solver.

In cases where the capabilities of quantum annealing solvers are exceeded, we introduce for the Stable Set Problem a specialized decomposition technique, which effectively breaks down the input graph

into smaller graphs, rendering them more manageable for quantum annealers. Finally, we conduct a thorough assessment of both quantum solvers alongside a classical simulated annealing solver. Our extensive numerical evaluation on various families of benchmark graphs demonstrates that the simulated annealing approach remains highly competitive. This competitiveness is primarily attributed to its simplicity and computational efficiency compared to quantum solvers.

5 - Quantum annealing approach for scheduling a job shop with availability constraints

Riad Aggoune, Samuel Deleplanque

Quantum optimization represents a rapidly evolving domain of research. It involves leveraging quantum computing systems and algorithms to address NP-hard problems. It generally requires the modeling of these problems in the form of Quadratic Unconstrained Binary Optimization (QUBO) models. The limitations of current quantum computers, particularly in terms of number of available qubits and their ability to handle variables, make it significantly challenging to develop optimization models that accurately reflect real-world constraints. In this paper, we consider the job shop scheduling problem subject to machine availability constraints. We propose a quantum annealing solution adaptable to both scenarios where machine unavailability periods are predetermined and when they are variable. It is based on a mathematical representation of the job shop scheduling problem formulated as a QUBO model [1]. The latter is derived from the first quantum annealing solution targeting the minimization of the makespan, introduced in [2].

Simulation of organizations II

Stream: Agent-based Models in Management, Economic and Organisation Sciences

Invited session

Chair: *Stephan Leitner*

1 - Designing Organizations for Resilience: Decision-Making Modes and Incentive Mechanisms

Stephan Leitner

In today's rapidly changing world, organizations are confronted with an environment marked by constant shifts and uncertainty, driven by factors like rapid technological progress and geopolitical instability. In such circumstances, the ability to adapt and thrive becomes crucial for an organization's survival. While some organizations display impressive resilience in the face of challenges, others struggle to cope with disruptions. Organizations that can swiftly respond to emerging challenges and seize new opportunities are often better equipped to navigate turbulent times successfully. However, building resilience is not just about reacting to external pressures; it also involves proactively shaping organizational structures and processes to enhance adaptability.

This study seeks to shed light on the mechanisms that drive organizational resilience, with a particular focus on key design elements such as decision-making modes and incentive mechanisms. Using agent-based modeling and simulation, the study aims to explore how these organizational design factors interact and influence resilience. Preliminary findings suggest that these design factors significantly impact an

organization's resilience, with the effects being moderated by the complexity of tasks. By exploring these dynamics, this research contributes to our understanding of organizational resilience and provides insights that can inform strategies for mitigating vulnerability.

2 - Human Digital Twin for Improving Occupational Health and Safety

Hanane El RAOUI, Le Khanh Ngan Nguyen, Ian Belton, Nathan Thompson, Mohamed Elawady

Human-centricity is central to the transition to Industry 5.0, prioritizing diverse human needs from health and safety to personal growth. In Industry 5.0, digital twins (DT) play a key role in seamlessly bridging the physical and virtual realms. While these virtual replicas enhance process safety, they often short in providing a comprehensive overview of safety issues. Various human factors contribute to the emergence of risky behaviours among workers, thereby posing significant threats to health and safety. Recognizing this reality underscores the imperative for integrating human elements within digital twins. In the industrial field, there's a noticeable lack of comprehensive exploration into the digital twins of workers, mainly stemming from a prioritization of production efficiency over human needs. The proposal of the Human Digital Twin (HDT) emerges as a critical approach to realizing human-centricity in Industry 5.0. HDTs, serving as digital counterparts of humans, aim to revolutionize human-system integration by establishing a direct connection between human characteristics and system design and performance. However, the exploration into advancing HDT development to redefine human roles and unlock full potential remains limited. This research aims to investigate the role of the human digital twin as an enabler of human-centricity in the industry. It proposes an HDT framework from a human factors perspective, promoting human safety and well-being in Industry 5.0.

3 - A model of burnout contagion in organizational settings

Claudia Estevez

Burnout is a syndrome recognized by the World Health Organization as an occupational phenomenon that costs billions of dollars in healthcare each year. Burnout manifests itself through symptoms of emotional exhaustion, psychological distancing, and a lack of personal accomplishment, which have been related to a variety of negative individual, group, and organizational consequences. More recently research has provided empirical evidence that burnout can be contagious. Explanations behind this contagion suggest that the emotions of an employee transfer via direct contact with other members of the group, a simple within-groups diffusion process. However, if this were the only mechanism behind burnout contagion, burnout levels of work group colleagues should be similar, which is not what is seen in real data.

Given this contradiction, in this research, I build an agent-based model of burnout contagion considering individual-level variables, both in-group and outgroup interactions, and different mechanisms as possible paths to the diffusion of the syndrome. Model results are then compared to real burnout data collected using an electronic survey from 1800 employees in an organization. Results shed light on the underlying complexity of burnout contagion and give support to claims for a dynamic understanding of the phenomenon. This will mean moving from more traditional and individualistic research approaches to more complex ones that match the nature of the phenomenon.

1 - Java Framework for Evolutionary Computation and Multiple-Criteria Decision Analysis

Michał Tomczyk, Miłosz Kadzinski

We introduce a novel Java framework for Evolutionary Computation and multiple-criteria Decision Making named JECDM. It predominantly focuses on facilitating research on a joint area of preference-driven evolutionary multi-objective optimization. From the programmer's perspective, the main features of JECDM are as follows. Firstly, we were focused on efficiency during the development to guarantee a low computational burden imposed when executing the code. Second, the code is highly object-oriented, facilitating readability, reusability, modularity, and low code redundancy. Thirdly, we reduced the use of external libraries to a bare minimum, securing the framework's self-sufficiency. From the practitioner's viewpoint, our framework provides a vast spectrum of well-organized functionalities. They are categorized into several top-level modules dedicated to evolutionary computation, multiple-criteria decision analysis, visualization, and experimental validation. The framework is available online and free to use for academic purposes. We explain how to operate it in a series of extensive tutorials provided as PDF files accompanied by code examples that are published along with the framework. These tutorials, e.g., discuss the general structuring of the framework's components, show how to implement new algorithms by oneself or demonstrate how to design experiments even of an extensive nature without much effort spent.

2 - Better Decisions with Less Cognitive Load: The Parsimonious BWM

Salvatore Corrente, Salvatore Greco, Jafar Rezaei

Despite its recent introduction in literature, the Best-Worst Method (BWM) is among the most well-known and applied methods in Multi-criteria Decision-Making. The method can be used to elicit the relative importance of the criteria as well as to get the priorities of the alternatives on the criteria at hand. Here, we will present an extension of the method, namely, the parsimonious Best-Worst-Method (P-BWM) permitting to apply the BWM to get the priorities of the alternatives in case they are in a large number. At first, the Decision-Maker (DM) is asked to give a rating to the alternatives under consideration; after, the classical BWM is applied to a set of reference alternatives to get their priorities used to compute, then, the priorities of all the alternatives under consideration. We propose also a procedure to select reference alternatives, possibly in cooperation with the DM, providing a well-distributed coverage of the rating range. In addition to the standard approach, we propose one alternative way of inferring the priority vectors in BWM and P-BWM based on the barycenter of the space of alternative priorities compatible with the preferences given by the DM. Finally, an experiment with university students has been conducted to test the new proposal. A comparison among BWM, P-BWM, the Analytic Hierarchy Process (AHP), and the parsimonious AHP in terms of the amount of preference information provided by the DM in each method to apply it is also given.

3 - Preference Learning Approaches in Interactive Multiple Criteria Decision Making Using Augmented Training Sets

Srinivas Prasad, Atilla Ay, Luis Novoa

We investigate machine learning based preference elicitation strategies in the context of Interactive Multiple Criteria Decision Making. Specifically, such methods employ popular machine learning techniques such as neural networks among others. We study how to make the training phase efficient in such an approach by employing certain preference representation structures that provide for augmentation of the training set. Such augmentations help accelerate the preference learning phase by making maximum use of the elicited preferences in eventually estimating the decision maker's preference profile based on partial preference information. We study different elicitation strategies in combination with different levels of augmentation and provide some empirical results illustrating their effectiveness.

4 - Setwise Preferences: A Case Study in High-Resolution EO Satellite Scheduling

Alex Vasegaard

In Operations Research and specifically for the high-resolution Earth Observation Satellite (EOS) scheduling problem, setwise preferences introduce both a robustness to the automation of decisions, but also a complexity that significantly expands the preference space making the elicitation and utilization of these preferences a formidable challenge. In EOS scheduling, which is crucial for disaster management, sustainability, agriculture, and security, large areas of interest are often subdivided into smaller image strips, where the value of obtaining adjacent image strips in close temporal proximity is significantly increased due to temporal dependencies between images, and consequently the value of obtaining a particular set is of higher value than just the individual images. This study introduces a novel representative approach designed to streamline the elicitation and integration process of setwise preferences by interpolating outranking results from a sampling technique. The adoption of this approach addresses the challenges posed by the large preference space of setwise preferences, offering a pragmatic approach to incorporating these critical considerations into fully automated decision-making systems. Consequently, this study contributes to the broader field of OR by providing a viable solution to the intricate problem of setwise preference elicitation and integration.

Speed Networking

Stream: Making an Impact
Invited session

Chair: Susanne Heipcke

Chair: Ruth Kaufman

1 - Speed Networking

Making An Impact

Meet your peers in a friendly, informal way, through discussions in groups of 2-3 persons with pairings changing after a fixed time span of a few minutes. OR is a team business, and knowing people you can turn to for ideas, feedback and support makes all the difference. But it is not always easy building your network, especially if you are shy or feel that you are an outsider. This welcoming session is a way of overcoming the barriers to networking, and enjoying yourself while you do it.

You may find it easier if you come with an idea of how you can introduce yourself to others in just two minutes. But don't worry if you don't have time to prepare - you'll soon pick it up.

If you have business cards, do bring them along; if not, we'll have plenty that you can use if you choose.

Monday, 10:30-12:00 - Room: 50 (building: 324)

MCDA applications in Engineering and Management 2

Stream: Multiple Criteria Decision Analysis
Invited session

Chair: Andrej Bregar

1 - Group MCDM Methodology for Cyber Attack Mitigation and Response

Andrej Bregar, Jose Luis Flores, Anas Husseis

Due to the high complexity and relevance of cybersecurity, efficient management of cyber attacks and threats is becoming a strategic technology trend. It elevates the resilience of ecosystems through the use of reactive and proactive strategies, which rely on standardized incident response procedures and the implementation of suitable mitigation countermeasures to prevent cyber attacks. The selection of actions is a multi-criteria problem encompassing technical and organizational aspects that must deal with benefits, costs, and the cascading effects between dependent assets. A group decision-making setting is required to incorporate the opinions of different experts on the information, business, and organizational levels. We hence introduce a comprehensive group decision-making process that helps security operations centres assess and choose cybersecurity actions. It applies the Delphi technique to unify the judgments of decision-makers and is aligned with the MCDM model that equivalently uses the quantitative or qualitative value function based on the standard scoring system. The veto function is also aggregated to prevent the selection of actions with an insufficient improvement in efficiency. The model considers criteria from the common CIA, ISO/IEC, and NESCOR standards. The framework utilizes the mappings between compromised assets, vulnerabilities, attack techniques, and responses. It further enhances analytics through external data sources and sensitivity analysis.

2 - Identifying Root Causes and Effects of RFID System Failures with Integration of AHP, DEMATEL, TOPSIS, DEA and FMCEA

Sahand Daneshvar, Khaoula Chnina

FMCEA (Failure Modes Causes and Effect Analysis) has long been utilized as an effective risk management approach across various industries for examining and assessing the failure modes of diverse products and processes. Nonetheless, this method exhibits several shortcomings associated with traditional RPN (Risk Priority Number) calculations, such as duplicate identification, gaps, and equal weighting of experts, as well as the lack of consideration for various factors like risk parameter weights, interrelationships, cost, and time and efficiency notions in risk assessment.

To overcome these limitations, a five-stage methodology integrating Analytic Hierarchy Process (AHP), Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS), Decision Making Trial and Evaluation Laboratory (DEMATEL), and Data Envelopment Analysis (DEA) with FMCEA is proposed. First, AHP assigns weights to experts, while FMCEA assesses failure causes considering occurrence, detection, severity, cost, and time. DEMATEL weights risk factors and explores their interrelationships. TOPSIS calculates RPNs. DEA measures efficiency and establishes interrelation matrices. DEMATEL ranks sub-failure modes based on their interrelationships. Finally, an aggregation procedure combines related sub-failure modes. The RFID system is used as an example to illustrate the methodology to show the advantages of the proposed approach.

3 - An Enhanced Simulation-Based Approach for Multicriteria Evaluation Problems

Pappalardo Maria Rosaria, Silvia Angilella, Michalis Doumpos, Constantin Zopounidis

The sigma-mu efficiency methodology, derived from Stochastic Multi-Attribute Acceptability analysis (SMAA), addresses uncertainty in decision alternatives' performance by constructing Pareto-Koopmans efficiency frontiers (Greco et al., 2019). These frontiers evaluate alternatives based on expected performance μ and variability σ , across diverse criteria weights. In this paper, we assess alternatives' performance by synthesizing the distribution of composite indicator values, incorporating additional parameters beyond μ and σ , namely, skewness and kurtosis. These parameters offer valuable insights into the shape characteristics of the probability distribution of composite indicators, i.e. tailedness and symmetry. Therefore, in this study, we propose revisiting the SMAA model by adopting the versatile Dirichlet distribution to the weights of the criteria (Saint-Hilary, et al., 2017; Jia et al., 1998). The Dirichlet distribution, thanks to its flexibility in representing shapes,

incorporating prior knowledge, and supporting the simplex, is deemed suitable for modeling weights' uncertainty without expert elicitation and capturing skewness and kurtosis based on shape parameters α and β . The proposed approach is employed to evaluate the European Small and Middle-Sized Enterprises' (SMEs) performance from 2018-2022 using financial, qualitative, and ESG criteria, creating a comprehensive composite indicator aligned with the sustainable goals of Agenda 2030.

DEA and Machine Learning

Stream: Data Envelopment Analysis and its Application
Invited session

Chair: María D. Guillén

1 - Exploratory benchmarking with DEA and multidimensional scaling - process, reference model and application

Steffen Hoffmann

Benchmarking is a valuable process for improving strategic and operational decisions in both profit and non-profit organizations. An important sub-process of benchmarking is to measure performance gaps and uncover their causes. While Data Envelopment Analysis (DEA) can handle the evaluation part, Data Mining tasks are suitable to explore the link between computational results and additional knowledge. Therefore, a new Data Mining process called Exploratory Benchmarking is proposed. The process integrates DEA and Multidimensional Scaling (MDS) as a reference model to structure decision support using well-researched methodologies. First, the role of DEA is to evaluate the related data in context. Next, MDS is used to visualize the results of the evaluation. Finally, a systematic analysis is performed to uncover manifest and latent structures using a specially developed exploration procedure. The entire process is exemplified by a real-world application in the field of air navigation service providers at airports. However, the approach can be applied far beyond this as a standard process in business analysis and consulting.

2 - Simulating Data Envelopment Analysis with Machine Learning: A Clustering-Based Data Preprocessing Technique for Training Set Selection

Barbara Kaminska, Dimitrios-Georgios Sotiros

Data Envelopment Analysis (DEA) is a non-parametric technique for measuring the relative efficiency of a set of decision making units (DMUs), on the basis of multiple inputs and multiple outputs. Performing a typical analysis with DEA requires to solve a series of linear programs, one for each DMU. Therefore, DEA suffers from the curse of dimensionality, i.e., on big data the computational load is very high. This issue is commonly treated in the literature with the adoption of Machine Learning (ML) algorithms. Nevertheless, even though the selection of the training dataset is of crucial importance in such algorithms, in the DEA literature this factor is neglected and all methods rely on random sampling. In this paper, we built on the existing literature and we introduce a clustering-based data preprocessing technique to select the training dataset in a way that it represents the entire dataset as much as possible. We use simulated data to test this new technique against random sampling under different ML algorithms, number of netputs and standard DEA models. We further test it on a network DEA model for two-stage series structures in which the efficiency scores are represented in a two-dimensional vector. In all cases, the results highlight that the proposed technique increases the accuracy of the ML algorithms, whereas it may even decrease the required computational load.

3 - Improving the estimation of production functions through machine learning: a gradient boosting approach

María D. Guillén, Juan Aparicio

Making accurate predictions of the true production frontier is critical for reliable efficiency analysis. However, traditional deterministic non-parametric methods like Free Disposal Hull (FDH) or Data Envelopment Analysis (DEA) provide approximations of the production frontier that suffer from overfitting, systematically underestimating firms' inefficiency and yielding inaccurate predictions of the output. In this work, we propose a new approach that, following the machine learning paradigm, provides a more accurate prediction of the underlying true production frontier by adapting the Gradient Tree Boosting algorithm to the production context. We prove that the new estimator satisfies certain required regulatory conditions such as envelopment of data and monotonicity. The performance of the new models is evaluated through a computation experience that shows the outperformance of the new approach in terms of mean squared error and bias in relation to the standard techniques. Moreover, we show how to calculate different efficiency measures using the estimator determined through the new algorithm. Nevertheless, from a computational point of view, the new approach presents thousands of decision variables, making it computationally complex to solve. To tackle this problem, we also propose and check a heuristic approximation for the exact measures.

Integrated lot-sizing problems

Stream: Lot Sizing, Lot Scheduling and Production Planning
Invited session

Chair: Silvio Alexandre de Araujo

1 - Population-based search algorithms for an integrated scheduling problem in the pharmaceutical two-stage supply chain

Byung Soo Kim, Seung Jae Lee

This paper addresses an integrated scheduling problem in the pharmaceutical two-stage supply chain. The problem is composed of multiple pharmaceutical orders, multiple unrelated factories, and one distribution center. Each factory uses a distinct permutation flow shop line consisting of hybrid batch/continuous processes and considers sequence-dependent change-over time. The distribution center picks up the products by truck shipment. The objective function is to minimize the makespan. Lot sizing, assigning, and production and truck shipment sequencing processes are the main decisions for the addressed problem. A mixed integer linear program is developed, and two types of population-based search algorithms are proposed to effectively and efficiently find the near-optimal solutions for the large-sized instances. In the small-sized experiments, the performances of the algorithms are verified by the absolute comparison with the mixed integer linear program. In the large-sized experiments, the performances of the algorithms are evaluated by the relative comparison.

2 - Integrated Scheduling of Continuous Casting and Hot Rolling in Steel Production: Modeling as a Two-stage Lot Sizing/Assignment Problem

Hubert Missbauer, Alexander Lohr, Julian Fodor

Scheduling of the sequential production stages Continuous Casting and Hot Rolling in steel production for a time horizon of about 7 days is a complex problem that requires considering technical constraints at both stages as well as limited capacities of upstream facilities (steel-making and refining) and intermediate stages (slab processing and heat

preservation pits). Due to this complexity, decomposition is required to handle the problem. Based on the case of an Austrian steel plant we elaborate on the decomposition principles applicable, mainly temporal decomposition and two-stage block planning, where the former seems to be closer to practical applicability. In our research we pursue the latter. We show that the technical characteristics of the two stages lead to a combined two-stage lot sizing and slab assignment problem that can be solved by a fix-and-relax heuristic using a MILP solver. The sequencing problem on the continuous casters and the determination of start and completion times of the casts and of the rolling turns (timing) must be solved subsequently due to the problem decomposition. Numerical experiments indicate that the sequencing problem can be solved well by established methods provided that appropriate constraints are formulated at the lot sizing/assignment stage. The timing problem can be solved by resource-constrained project scheduling methods, but the capacity constraint of slab processing requires extension of the scheduling method we selected.

3 - Hybrid Biased Random Key Genetic Algorithm For The Capacitated Multi-Period Cutting Stock Problem with Setups

Eduardo Silva, Silvio Alexandre de Araujo, Antonio Chaves, Raf Jans

The Multi-Period Cutting Stock Problem (MPCSP) involves cutting large stock objects into small items to satisfy demands for each period while allowing for inventory. The MPCSP is a variation that integrates the well-known Cutting Stock Problem (CSP) and the Lot-Sizing Problem. Practical applications are found in the furniture and paper industries.

In CSP, the primary goal is to minimize material costs. However, real production involves auxiliary costs, like switching between cutting patterns, causing interruptions and setup costs. A desirable cutting plan has fewer patterns. Literature on pattern setups in MPCSP is limited, and when capacity constraints are considered, the problem becomes even more challenging.

Pattern-based models and column generation are common approaches for MPCSP along with another heuristics. A large number of columns in practical problems is a challenge for pattern-based models, making techniques like evolutionary algorithms an alternative approach.

This work proposes a Biased Random Key Genetic Algorithm (BRKGA) optimized by Q-Learning (BRKGA-QL) to solve MPCSP with capacity constraints and pattern setups.

The BRKGA-QL is compared with a hybrid column generation approach from the literature using benchmark instances. Results show BRKGA-QL consistently outperforms in terms of integer values across all instances.

4 - Integrated lot-sizing and cutting stock problem applied to lattice slab production

Silvio Alexandre de Araujo, Caroline de Arruda Signorini, Raf Jans

In the construction industry, lattice joists (referred to as an "item" in this study) are precast structures that combine a steel truss with a concrete base. Their production is based on a client's order that specifies the quantity, length, and deadline for delivery. A process manager uses this information to create a weekly production plan that determines the number and type of items to produce in each period. This study considers a real-world production planning problem in a Brazilian lattice slab factory. The primary concerns of the factory include minimizing the waste of steel trusses and optimizing setups and inventory. Decisions regarding purchasing steel trusses (objects) and managing stocks in different sizes are also considered. We propose two alternative mathematical formulations for this integrated lot sizing and cutting stock problem. Additionally, solution strategies are proposed to address the resulting mixed-integer programming models. Computational tests are conducted to evaluate the effectiveness of the proposed model and the solution approaches.

Retail Inventory Management I

Stream: Retail Operations

Invited session

Chair: *Rob Broekmeulen*

1 - Integrating time-temperature dependent deterioration in an EOQ-based methodology for perishable products in multi-echelon supply chains

G.D.H. (Frits) Claassen

Literature shows that order-level inventory systems for perishable items are often modelled by parametric approaches e.g., a time-dependent (Weibull) deterioration rate. In practice however, product deterioration for perishable products is a complex process, highly product dependent and, crucially, depending on environmental conditions from origin to final destination in supply chains. We develop a generalizable concept for order-level inventory systems in multi-echelon supply chains in which product-specific deterioration is derived from biological sciences. We take time-temperature-dependent deterioration, and multi-echelon supply chains into consideration and integrate both aspects into a generically applicable EOQ-based methodology. We demonstrate the concept from a real-life case study for cold chain management in floriculture. Two common multi-echelon cold chains for cut roses in practice are considered and compared. The results show that the optimal order levels for different actors in the supply chains are substantially different. In addition to the sojourn time, the temperature has a major impact on order levels, the total supply chain costs, and the remaining shelf-life at retail level. We demonstrate that the proposed concept for extending the EOQ-based model to time- and temperature-dependent deterioration can be easily generalized and applied to other specific causes of product-dependent deterioration.

2 - Shelf-life requirements and their impact on contractual agreements in perishable-product supply chains

Sandra Transchel, Mahyar Tahery, Andreas Gernert

Two primary goals of grocery retailers when managing perishable products (e.g., food) are (i) to offer products with a high remaining shelf life to consumers, as those are perceived to be of high quality, and (ii) to minimize waste driven by products that exceed their maximum remaining shelf life. Both goals prompt retailers to integrate a minimum remaining shelf-life requirement, known as "Minimum Life on Receipt" (MLOR), into the contracts with their suppliers. However, little is known about how such an MLOR requirement affects the contractual agreement between retailers and food producers and how it further affects replenishment and production decisions, profitability, and waste of the retailer and the food producer. In this paper, we investigate how an MLOR requirement of the retailer affects the operational performance of a wholesale price contract in a two-echelon perishable-product supply chain. We consider that both the retailer and the food producer follow a basestock policy, where the basestock levels are optimized depending on the wholesale price set by the food producer and the MLOR requirement. Our results challenge widely accepted findings that retailers benefit from organizing their inventory management following a first-in-first-out (FIFO) issuing policy compared to a last-in-first-out (LIFO) policy.

3 - Definition of the MLOR rule through a bilevel optimization model

Maria João Santos, Sara Martins, Pedro Amorim

The Minimum Life On Receipt (MLOR) rule is established by retailers to impose the maximum age a perishable product can be accepted upon reception. Such a rule tends to be rigid but allowing the rule's flexibility may bring benefits for both producer and retailer. The objective of this work is to investigate such benefits. The problem will be represented by a bilevel optimization model where the retailer is the leader, and the producer is the follower. In this problem, the rational response of the producer is to either comply with the fixed MLOR rule

imposed by the retailer or offer a discount to the retailer's orders whenever he/she is willing to adopt a flexible rule. An instance composed of a perishable product with 3 days of shelf life and a time horizon of 3 periods is used to enumerate all possible solutions for the problem. The solutions are examined in terms of profits and waste generated. Afterwards, an exact solution method is developed through single-level reformulation aiming to solve the general problem.

4 - A novel competitive model for production and distribution planning of deteriorating products under uncertainty: a case study

Adel Aazami, Sebastian Kummer

This paper develops a new robust optimization model for production and distribution planning considering competition among supply chains. The model maximizes the profit of a production and distribution corporation providing deteriorating products. The corporation's market share is enhanced by concentrating on freshness, some encouraging policies, and competitive characteristics. The model considers price, distance, and service level the most critical competitive characteristics. Regarding these characteristics, Huff's gravity model is developed to assess retailers' behavior better and compute market share rightly. Therefore, a mixture of compensatory and non-compensatory approaches considering the comparative attractiveness associated with each characteristic is devised to estimate the final utility of the regarded corporation for the retailers. Also, a robust optimization method is used to cope with the uncertainty. Due to the NP-hardness of the problem, an adaptive large neighborhood search algorithm is suggested. The model's performance is analyzed by solving a real-world industrial case study. Based on the computational examination, employing this study can seriously increase the corporation's profit by improving its market share.

Market risk in a volatile world

Stream: Risk management in finance
Invited session

Chair: *Aleš Kresta*

1 - Sparse Vine copula-based portfolio optimization

Illia Kovalenko, Thomas Conlon, John Cotter

This paper studies the use of the Regular Vine copula models in the context of the construction of portfolios with varying sizes. We find that copula-based portfolios outperform the naïve equally-weighted benchmark before transaction costs. Significantly reduced tail risk makes copula-based portfolios especially desirable for investors with high risk aversion. The superior performance is more pronounced during periods of high dependence asymmetry and high market volatility. Sparse vine models, in which independence pair-copulas prevail, provide significantly improved results for large portfolios across various performance measures, specifically reducing turnover. The improvement of portfolio performance, however, is attenuated as we take transaction costs into account. Limiting large portfolio turnover by increasing investment horizon or rebalancing error tolerance restores the outperformance of copula-based strategies.

2 - Comparison of risk-minimization portfolios with cardinality constraints and period lengths

Aleš Kresta, Qian Gao

In this study, we empirically compare the performance of portfolios optimized to minimize selected risk measures under a cardinality constraint. The chosen risk measures include standard deviation, semi-deviation, minimax, mean absolute deviation, maximum drawdown, conditional value at risk, and entropic value at risk. Additionally, we

introduce different values of the cardinality constraint and vary the period length used for parameter estimation in the portfolio optimization problem. This approach allows for a comprehensive comparison of risk-minimization portfolios, taking into account the selected risk measure, cardinality constraint, and period length simultaneously. Furthermore, we evaluate portfolio performance under various market conditions, specifically in the United States, Germany, and Chinese stock markets. Evaluation metrics include the Sharpe ratio, the Sortino ratio, and the Calmar ratio. The results reveal that no single risk measure dominates the others, and significant differences exist among them. Although the durations of optimal estimation periods vary for different risk measures, certain patterns emerge from the findings.

3 - Competition in Liquidity Provision: Analysis of High Frequency Market Making and Policy Implications

Katsumasa Nishide, Takaki Hayashi

We construct a financial market model wherein market makers post limit orders to compete for liquidity. We show that market makers may relinquish liquidity provision because of competition if the fundamental value of the asset is volatile. Besides the general perception that cancellation harms market liquidity, we find that cancellation can sustain liquidity and prevent depletion. Moreover, this finding, as well as others, leads to an important policy implication that the cancellation strategy, one of the most prominent characteristics of high-frequency trading, can positively affect market liquidity and should not be strictly regulated.

Combinatorial optimization approaches for freight deliveries

Stream: Combinatorial Optimization
Invited session

Chair: *Claudia Archetti*

Chair: *Yanlu Zhao*

1 - Freight-on-Transit for urban last-mile deliveries with road transportation and metro line

Yanlu Zhao, Mingda Liu, Zibo Zhang, Yixiao Huang

In this study, we explore the integration of cargo delivery into public transportation as an innovative and eco-friendly approach for city-based last-mile deliveries. This freight-on-transit (FOT) study, is driven by a prominent courier company's (SF Express) vision for a future where freight is transported via metro systems in Beijing, aiming to utilize the most of idle metro carriage space. The complexity of this hybrid road-subway delivery system, which needs to adhere to specific time schedules and split delivery, makes it a challenging problem to solve. To tackle this, we formulate it as a mixed integer programming model and develop an exact algorithm within a branch-price-and-cut framework. This method is capable of achieving near-optimal solutions efficiently. Our real-world data testing demonstrates that our strategy significantly outperforms the company's existing delivery strategies. In addition, we conduct various policy tests to assess the impact of dynamic dispatching and routing, considering changes in the size of the delivery fleet and the frequency of dispatches.

2 - Pricing and bundling decisions considering driver behavior in crowdsourced delivery

Alim Buğra Çınar, Claudia Archetti, Wout Dullaert, Markus Leitner, Stefan Waldherr

Crowdsourced delivery utilizes the services of independent actors. As opposed to traditional modes of delivery, availability and acceptance decisions of crowdshippers are uncertain and cannot be fully controlled by an operator. We consider a setting in which an operator groups tasks into bundles and in which the resulting bundles are offered to crowdshippers in exchange for some compensation. Uncertainty in the crowdshippers' behavior who may accept or reject offers is considered

via (individual) acceptance probabilities. We consider generic probability functions whose main parameters are the compensation offered, the number of tasks in a bundle, and the total detour to deliver a bundle. The objective of the resulting optimization problem is to minimize the expected total cost of delivery. We propose a mixed-integer non-linear programming (MINLP) formulation that simultaneously decides how to group tasks into bundles, which bundles are offered to which crowdshipper, and the compensation offered for each bundle. We show that this MINLP can be reformulated as a mixed-integer linear program with an exponential number of variables. We present a column generation algorithm for solving instances of the latter whose pricing sub-problem corresponds to an elementary shortest path problem with resource constraints (ESPPRC) and a nonlinear objective function. Our experiments show that the algorithm is capable of solving large instances.

3 - Exact approaches for the green commodity-constrained split delivery vehicle routing problem

Kamyla Ferreira, Claudia Archetti, Diego Delle Donne, Reinaldo Morabito, Pedro Munari

We address the Green Commodity-Constrained Split Delivery Vehicle Routing Problem (GC-SDVRP), which involves designing efficient and environmentally friendly delivery routes that reduce the carbon dioxide (CO₂) emission associated with the transport of multiple commodities. The GC-SDVRP considers that different types of commodities are available at the depot, and each customer has specific demands for different types of commodities. Multiple vehicles may visit a customer to deliver different types of commodities, as long as all commodities of the same type are delivered by the same vehicle, thus reducing customer inconvenience caused by split deliveries. Despite its practical relevance, the green variant of this problem has not been studied in the literature so far. In this talk, we introduce the GC-SDVRP and propose a branch-and-cut approach that is based on the solution of a relaxed formulation that provides a lower bound on the optimal value. Additionally, we adapt two other formulations from the literature. The results of computational experiments using benchmark instances indicate the effectiveness of our proposed method, which outperforms the results of other approaches. Our computational experiments show that minimizing emissions does not necessarily imply minimizing the travel costs, and vice versa. Moreover, it is computationally easier to solve the problem with CO₂ emissions than with the traditional objective of minimizing travel costs.

Crew Planning in Public Transport

Stream: Public Transport Optimization

Invited session

Chair: *Bart van Rossum*

1 - Integrated railway train unit and crew scheduling using column pre-generation

Chuhan Yin, Zhiyuan Lin, David Watling

In passenger rail operations, train unit and crew scheduling are key processes. Train unit scheduling assigns rolling stock, while crew scheduling allocates personnel like drivers. Both tasks, critical for optimizing vehicle and crew use to save costs, are complex NP-hard problems traditionally solved separately as two stages. This sequential approach limits achieving truly optimal schedules. An integrated approach, considering both simultaneously, promises more optimized solutions and has been successful in bus operations, reducing operational costs and crew usage, but is under-researched in rail planning. In this study, we introduce an integrated approach for scheduling train units and crews by utilizing pre-generated shifts (duties). This approach faces unique obstacles in the rail sector, particularly when employing the pre-generation strategy. A key challenge involves allocating staff

to auxiliary tasks like shunting and unit coupling/decoupling, which are determined during the integrated process but unknown in advance. Another challenge is the need to pre-generate deadheading trips and incorporate them into pre-generated shifts. This challenge does not exist during the separate procedure. In theory, there is a huge number of deadheading trips, leading to a severe increase on the number of pre-generated shifts. We explore solutions to these issues through both synthetic and real-world examples, demonstrating our approach's effectiveness in solving these challenges.

2 - Robustness in railway crew scheduling

Paul Paprer, Janis Sebastian Neufeld, Udo Buscher

Traction unit drivers have become an increasingly critical resource for railway companies, making the railway crew scheduling problem an essential step in the planning cascade. While efficiency has traditionally been the primary goal, the vulnerability of schedules to disruptions requires robust planning. Compared to other planning stages in the railway sector, crew scheduling robustness has received less attention, although its counterparts in the bus and airline industries are thoroughly evaluated. We address this gap by investigating robustness in railway crew scheduling problems and its impact on efficiency. Our approach involves solving real-world problems using column generation. We assess existing robustness indicators and adapt a performance indicator from timetabling called t-robustness. This criterion is new for crew scheduling. On the one hand, t-robustness penalizes train changes, which are critical since delays are transferred to other circulations. On the other hand, buffers at important spots within a shift are rewarded. We evaluate the dependencies between efficiency and robustness through empirical analysis of real-world planning problems, highlighting the significance of our proposed t-robustness measure. By integrating robustness considerations into crew scheduling, railway operators can achieve shift plans that not only optimize efficiency but also better withstand unforeseen disruptions, ensuring resilient operations.

3 - Benders Decomposition for Robust Tactical Crew Scheduling

Bart van Rossum, Twan Dollevoet, Dennis Huisman

We consider robust tactical crew scheduling for a large passenger railway operator, whose timetable is subject to minor but uncertain updates on a weekly basis. Before the start of the planning period we must select a number of templates, specifying the time windows in which crew is supposed to work. These templates must be cost-efficient whilst providing sufficient capacity for the realised updated timetables. Moreover, the templates must be compatible with the rostering process, i.e., we wish to limit the number of different templates used and ensure that there are not too many templates on early or late moments of the day. Throughout the planning period, the templates are assumed to be fixed and the updated timetable is released on a weekly basis. All tasks in the timetable must be covered using the capacity provided by the templates, or, if necessary, costly reserve capacity. We model the template selection problem as a scenario-based robust optimisation model, for which we propose a Benders decomposition algorithm. We conduct computational experiments on real-life instances from Netherlands Railways and show that our algorithm is able to solve instances featuring up to three scenarios and up to 1,000 tasks per scenario to optimality. Including more scenarios, allowing for more flexibility in choosing templates, or enlarging the template length all lead to reductions in reserve crew costs without increasing template-based crew costs.

Transportation Network Modelling and Optimization II

Stream: Transportation

Invited session

Chair: *Luca D'Acerno*

1 - Time-constrained hub-based networks: Designing beyond location-allocation

Ana María Anaya-Arenas, Esteban Ogazón, Angel Ruiz

Hub-and-spoke problems have been widely studied in the literature and as they are more of a strategic problem, little effort has been devoted to incorporating service-related restrictions into them. However, current trends in transportation seek more flexibility and tighter service schedules. In this talk we will discuss the nuances of integrating time constraints into hub-and-spoke systems. Two alternative and efficient formulations for hub network design with strict time restrictions and service levels will be presented. To illustrate our contribution, a case-study inspired from the healthcare network of Québec, Canada, will allow us to show the interest and importance of considering this restriction explicitly in the model.

2 - Coordinated Passenger Flow Control into Urban Rail Transit Systems to Mitigate Overcrowding during large-scale Events

Knut Haase

Responsible policymakers and transportation planners must ensure safe transportation during large-scale events, especially in urban rail transit systems that are not designed to handle high demand, as overcrowding can lead to dangerous situations and even fatalities. This paper presents an approach to optimize the number of passengers allowed into urban rail transit systems, considering the limitations of trains and station platforms, while also ensuring that as many people as possible can be transported. To achieve this, we developed an optimization model embedded into an iterative heuristic that incorporates the predicted demands, real time-data and the capacity limitations of the entire system. To ensure the accuracy and robustness of our model, we evaluated our approach on a data set based on a comprehensive transportation demand simulation. Our results indicate the effectiveness of our approach. By iteratively optimizing the allowance, we can achieve a good balance between the capacity utilization and the number of people transported. Our system can assist policymakers and transportation planners to control the passenger flows and thereby prevent overcrowding and accidents.

3 - The influence of passenger weight on rail and metro running times: Theoretical formulation and applications to the case of Line 1 of the Naples metro system (Italy)

Luca D'Acerno, Luca De Matteis, Rosario Stefanelli, Marilisa Botte

Analyses of transport systems require knowledge of the interactions between travel demand and transport system performance. In general, the travel demand depends on transport system performance, and in turn the transport system performance depends on how many users use the same element at the same time. In the literature, rail and metro systems are generally considered uncongested (i.e. performance does not depend on the travel demand) at least as regards train running times. This contribution examines the dependence of train running times on the number of transported users. Indeed, in rail and metro contexts, the weight of carried passengers in the case of a full load has the same order of magnitude as the unloaded train weight. Hence, variation in the maximum traction effort and the motion resistance between a fully loaded and a completely empty condition implies variations in train running times. Moreover, in frequency services, even in the case of constant demand (i.e. rigid demand assumption), the number of users boarding each train depends on the service frequency. Hence, since service frequency depends on the running times through the cycle time, it is possible to identify a fixed-point problem between the number of boarding passengers and train running times. The application to the case of Line 1 of the Naples metro system has shown the extent of these variations and the extension times conditions that allow defining a cycle time independent of demand variability.

4 - A Variable Fuel Consumption Curve in the Tramp Ship Routing and Scheduling Problem

Sahar Moazzeni, Gabriel Fuentes, Julio C. Góez

This study explores tramp shipping operations, where efficient fuel management is important for financial success, environmental responsibility, and global sustainability goals. The paper focuses on integrating speed-dependent non-linear fuel consumption curves into the basic tramp ship routing and scheduling problem, recognizing the need for precise fuel consumption estimation. A non-linear mixed integer programming model is proposed for routing, scheduling, and speed optimization. The model is to study the impact of variable elasticities across different speed intervals, aligning closer to the complexities of a per vessel-specific fuel consumption. Finally, we will examine the impact of introducing speed and specially speed-dependent fuel-speed elasticities and calculate the time charter equivalent as an economic measure, based on the outputs of the model with constant elasticity and the model with speed-dependent elasticity.

Freight railway transportation

Stream: Transportation

Invited session

Chair: Ricardo Garcia-Rodenas

1 - Scheduling shared passenger and freight transport for high-speed railway networks

Siqiao Li, Li Wang

This study investigates the potential for a shared freight and passenger system to effectively utilize the remaining capacity of high-speed railway networks after serving passenger demand. Two sharing modes, which determine the mixing of passenger and freight flows, are considered and jointly optimized. A space-time network is constructed to capture the passenger/freight trajectories on an existing schedule. A penalty cost based on train load factors is introduced for each trip to represent the influence of shared transportation upon passenger satisfaction, which allows us to analyze the interplay between passenger and freight flows. The model is first formulated as a mixed-integer program that minimizes service and routing costs and then reformulated into a path-based model. A Benders decomposition approach is proposed to decompose the problem into two subproblems. A column-pool-based approximation approach is proposed to efficiently generate space-time paths and obtain good upper bounds. Two tailored acceleration techniques are presented to overcome the problems of slow iteration and wild oscillation. The developed algorithm is tested on 2 small-scale cases and 12 large-scale cases. The computational study provides insight into how the optimal network is affected by the train load factor, penalty cost, sharing mode, and commodity volume.

2 - Determining the optimal Point in Time and Duration of Track Possession Times

Yannick Burmeister, Arturo Crespo Materna, Andreas Oetting

While track possession times (due to railway construction and maintenance works) for the most part render portions of the railway infrastructure temporarily unavailable, they are necessary to upkeep the its long-term serviceability. Therefore, possession times and the construction processes themselves must be planned and executed in such a way as to minimize the impact on railway operations. This contribution proposes an approach to determine the optimal point in time and duration of track possessions with a focus on ETCS installation. The approach utilizes mathematical modeling techniques and a hybrid between an exact and heuristic method while considering effects on the railway operations, construction management requirements, and production resource constraints like available labor force. The proposed approach enables a better capacity consumption in the railway network by allowing an optimized planning of possession times and a faster realization of railway construction works. To validate the approach, the results are compared with real-world track possession time planning.

3 - A Hybrid Benders Decomposition for Multi-stop Railway Freight Loading and Unloading Problem

Chenhao Zhou, Xiaorong Ren, Li Xue

Railway freight transportation plays a crucial role in China's economic growth and has received substantial investment in railway infrastructure. The introduction of the high-speed freight train presents the logistics market with a competitive alternative between air and land transport. This new service enables cargo loading and unloading at various stops along the journey in order to maximize carriage utilization. Given the tight transit time at each stop, the high-speed freight service needs to allocate freights into different carriages without any remarshalling — such as removing existing freights before putting everything back — between freights. As such, the freights must be handled in a First-In-Last-Out (FILO) order and requires a careful plan of carriage assignment and storage allocation for each freight, which motivates this multi-stop railway freight loading and unloading problem. Considering the aforementioned operational features, a fresh variant of the bin packing problem (BPP) can be defined, i.e., the Temporal BPP with FILO policy (TBPP-FILO). This novel variant incorporates the sequential requirements of loading and unloading processes, presenting a unique and difficult challenge compared to existing BPP variants. A hybrid Benders decomposition approach is developed using the technique of Lagrangian relaxation, which adjusts the allowance of capacity violation through the update of Lagrangian multipliers.

4 - An Optimization Model for Determining Access Costs in Rail Freight Transportation

Ricardo Garcia-Rodenas, Esteve Codina, Luis Cadarso, Maria Luz Lopez, José Ángel Martín-Baos

The liberalization of European railway markets necessitates a vertical separation governance framework, with Infrastructure Managers (IMs) providing resources and Freight Operating Companies (FOCs) utilizing them. Effective pricing of track access between these entities is vital for profitability and system efficiency. Additionally, achieving a modal shift of freight from road to rail is crucial for road safety and EU objectives alignment. This paper introduces a novel pricing methodology for train paths, optimizing infrastructure utilization by IMs while considering competitive dynamics and environmental impacts. It addresses challenges such as elastic demand, integrating network capacity into pricing strategies, and managing non-additive costs and path interdependencies. The proposed model incorporates dynamic demand patterns, temporally variable capacities, and total revenue considerations across the planning horizon. A discretization-based approach, focusing on irregular time intervals and unit freight tonnage, is developed for solving the continuous model. This involves linking freight tonnage units to a prototype train, with a discrete event simulation model employed. The objective function is also discretized, yielding a finite set of optimization variables to be optimized subject to simulation model. An application of this approach is demonstrated through a case study of the Mediterranean Corridor.

utility where the expectation is taken with respect to both financial and preference uncertainty. That is based on Steffensen and Sørensen (2023). Another version is based on certainty equivalents. We tackle the time-consistency issues arising from that formulation by applying the equilibrium theory approach. The case where the investor learns nothing about his preferences as time passes is based on Desmettre and Steffensen (2023). We also discuss another case where risk aversion is an observed stochastic process.

2 - Value-at-Risk estimation in nested simulations

Alexander Strack

Since the ratification of Solvency II, the determination of the Value-at-Risk in the insurance industry has gained renewed importance. We examine the convergence of estimators of the Value-at-Risk or, more specifically, of quantiles within the nested Monte Carlo framework as they occur in the internal models of (typical life) insurance companies. Due to the numerous model uncertainties, robust methods and model-free results are of particular importance. To this end, we provide sharp results regarding the deviation of the quantiles of a perturbed random variable to the quantile of the undisturbed random variable depending on the perturbation, while reducing the assumptions to a minimum without sacrificing the sharpness of the results. These results are combined with classical results from estimation theory to derive almost-sure convergence rates for the Value-at-Risk estimator under rather weak assumptions.

3 - Catastrophe Risk Management

Tadashi Uratani

Serious disasters had occurred in Japan as Kobe earthquake, East-Japan Tsunami and Covid-19 and Noto earthquake of this year. The economic burden to recover from disasters is expanding government deficit further. Reinsurance and securitization such as catastrophe bond are analyzed for application to overcome future financial burden of disasters.

4 - The Value of Lender-Initiated Loan Credit Insurance in Supplier Financing

Hechen Zhong, Nina Yan, Jizhou Lu, Kin Keung Lai

Supply chain finance (SCF) solutions facilitate access to financing for small and medium-sized suppliers. However, in volatile market conditions, payment defaults among supply chain participants can affect the stability of SCF systems. To effectively mitigate default risks, financial service providers often purchase loan credit insurance (LCI) to transfer potential losses to insurers. When retailers cannot repay or default on their payment obligations, insurers will compensate the lender within the policy terms. Using a game-theoretical approach, we assess the value of LCI for the lender and the capital-constrained supplier. Our analysis reveals that the lender can benefit from LCI when the insurance deductible is relatively high, and the insurer's loading factor is relatively low. The capital-constrained supplier with higher capital investment and lower unit production cost can also benefit from LCI. Furthermore, when the insurance scale and loading factor are low, the supplier is more likely to increase profitability. However, the supplier can achieve superior investment efficiency in scenarios with higher insurance scale and loading factor, suggesting increased capital investment to benefit from LCI better. These findings underscore the value that the lender-initiated LCI can bring to capital-constrained suppliers, offering significant insights for small and medium-sized suppliers and financial service providers engaged in SCF practices.

1 - A new Simuheuristic for Stochastic Cross-Dock Scheduling Problem With Time Windows Under Uncertainty

Wei Yang, Yang Wang, Jin-Kao Hao

Cross-docking, a rapid logistics strategy, emerges not just as an option but as a strategic necessity in the era of just-in-time inventory and manufacturing systems. In this context, we study a novel stochastic cross-dock scheduling problem considering uncertain truck arrival times to minimize the total penalty of untransferred goods and truck departure delay. A new hybrid genetic simuheuristic framework is proposed that embeds a simulation-based local search into a variable neighborhood decent (VND) algorithm. VND optimizes on the deterministic version, in each iteration, if the current solution is identified as a promising solution (not necessarily a local optimal solution), SBLS, where the neighborhood is evaluated by the simulation instead of the deterministic objective value, is triggered in the expectation of finding a local optimal scheduling policy under the stochastic version. A fast evaluation technique for sample scenarios is designed, independent of the objective function, which allows the expectation of the objective under a given sample to be evaluated without simulation, thereby improving the efficiency of the search. And we extend the fast evaluation technique to scheduling problems with a similar structure. Finally, systematic experiments and analysis prove the efficiency of our proposed algorithmic framework and fast evaluation technique.

2 - Multi-Objective Shipment Consolidation and Dispatching Problem

Ozgur Ozpeynirci, Ozge Buyukdeveci, Selin Özpeynirci

In recent years, with the increase in global production and demand, transportation problems have become a widely studied area, and studies focus on providing high-quality service at the lowest cost. This study considers a bi-objective shipment consolidation and dispatching problem with the objectives of minimizing the total cost and the total distance. In order to create a non-dominated solution set, a multi-objective mixed integer linear programming model is developed and augmented epsilon constraint method is used to generate the non-dominated frontier. However, this approach is not capable of finding the non-dominated solution set in a reasonable time, even for small-sized instances, and therefore, we propose a multi-objective variable neighborhood search heuristic. To measure the performance of the proposed approach, a computational experiment is conducted on randomly generated instances available in the literature. The experimental results indicate that the multi-objective variable neighborhood search heuristic performs efficiently in reasonable time.

3 - New Reinforcement Learning Algorithms for Pickup and Delivery Routing Problems

King Tong Wong, Tsung-Sheng Chang, Jamal Ouenniche, Joosung Lee

The Pickup and Delivery Routing Problems (PDRPs) are challenging combinatorial optimization problems with significant real-world applications. This paper proposes new Reinforcement Learning (RL) methods to address this type of routing problems. The typical mathematical programming formulations and the existing solution methods are first presented. Then, the concepts of Reinforcement Learning (RL) and Deep Learning are introduced, and the PDRP is reformulated as a RL problem. Several RL algorithms including new proposals are discussed and their performance is compared to an exact solution. This research contributions include employing RL to solve PDRP and comparing various RL algorithms including new proposals.

4 - Hybrid Genetic Algorithm a new Perspective to Solving Capable Vehicle Routing Problem (CPVPR)

Lucas Contreras Rada, Helman Enrique Hernandez Riaño, Jorge Mario López Pereira

This study focuses on solving a capable vehicle routing problem (CVRP) using a genetic algorithm (GA). The CVRP is a complex optimization problem that often arises in supply chains when routing vehicles with different populations. The study proposes a new solution that uses a metaheuristic to optimize the implementation between crossover and mutation of new operators. These operators use different strategies to search for better solutions generated from an initial population. The CVRP is formulated as a mixed integer programming (MIP) problem, where the genes represent decisions about which customers to visit and which vehicles to use for the route.

The existing literature provides ample support for this issue, with many articles discussing the indicators and comparisons of experimental tests post-realizations that show the efficacy of the proposed algorithm. Through significant advances in the solution problem, the study obtained a GA-modified solution to the CVRP by adjusting different parameters to identify the most adaptable solution. The results were then compared with other solution methods as solvers focus on the same problem.

Revenue Management in Sharing/Platform Economy

Stream: Pricing and Revenue Management
Invited session

Chair: Dong Li

1 - Enhancing carsharing pricing and operations through integrated choice models

Selin Ahipasaoglu, Beatriz Brito Oliveira

Balancing supply and demand in free-floating one-way carsharing systems is a critical operational challenge. This paper presents a novel approach that integrates a binary logit model into a mixed integer linear programming framework to optimize short-term pricing and fleet relocation. Demand modeling, based on a binary logit model, aggregates different trips under a unified utility model and improves estimation by incorporating information from similar trips. To speed up the estimation process, a binning approach is used, where variables such as location and time are categorized into a few bins, which is particularly beneficial for trips with limited observations. The modeling framework adopts a dynamic structure where the binary logit model estimates demand using accumulated observations from past iterations at each decision point. This continuous learning environment allows for dynamic improvement in estimation and decision making. At the framework's core is a mathematical program that prescribes optimal levels of promotion and relocation. The framework then includes simulated market responses to the decisions, allowing for real-time adjustments to effectively balance supply and demand. Computational experiments demonstrate the effectiveness of the proposed approach and highlight its potential for real-world applications. The continuous learning environment, combining demand modeling and operational decisions, opens avenues for future research in transportation systems.

2 - Enhancing the performance of carsharing systems by optimizing multi-attribute pricing plans

Masoud Golalikhani, Beatriz Brito Oliveira, Gonçalo Correia, José Fernando Oliveira, Maria Antónia Carravilla

Carsharing operators commonly offer several pricing plans tailored for different customer profiles, constructed from various attributes such as registration, travel distance, and travel time fees. Each plan may have different rates across high/low demand periods and areas to increase fleet utilization and maintain a balanced supply-demand system. However, in most existing works, the heterogeneity of users is not considered, and plans consist of only a single attribute (i.e., travel time fee). In this study, we formulate a mixed-integer linear programming model with the objective of profit maximization to optimize multi-attribute plans with time- and location-dependent rates, considering customer preferences and travel behavior. A discrete choice model is incorporated to estimate customer response to the value of plan attributes. We utilize real-world data from the Brooklyn taxi trip dataset to validate results and provide managerial insights. Results demonstrate the effectiveness of this approach in improving system profitability, particularly through time- and location-dependent rates. The model can find the optimal or near-optimal solutions for real-sized problems within a reasonable time limit. Moreover, we developed an approximate algorithm to efficiently produce high-quality results for large-scale instances within a shorter timeframe. Finally, we delivered valuable managerial insights regarding customer segmentation, pricing plan complexity, and parameter sensitivity.

3 - Logistic Service Sharing between a Food delivery platform and an E-com platform

M Sivarama Anandha Krishnan, Rahul Marathe, Pradnya Karbhari

In e-commerce, a robust logistic service provides a competitive edge, necessitating significant investment. Many small businesses opt for third-party logistics to cut costs. Our study explores enhancing revenue for such platforms by examining the benefits of sharing logistic resources. Key questions addressed are: a) Is it advantageous for a food delivery platform (FDP) to collaborate on logistic systems with another e-commerce platform, considering its current operations? b) What is the impact of logistic sharing between a food delivery platform and an e-commerce platform on restaurant behavior? We developed a non-cooperative game model involving the FDP, a restaurant, an e-commerce platform, and third-party logistics. Both restaurant and e-commerce demands were considered stochastic variables. Two scenarios were evaluated: (1) Without sharing logistic resources between the food delivery and e-commerce platforms, and (2) With shared logistic resources. The aim was to determine the feasibility of resource sharing. The study identified the optimal commission rates from the restaurant and e-commerce platform to the FDP, the optimal marketing index and the optimal service level offered to the restaurant and e-commerce platform, respectively by the FDP, through solving a Stackelberg game-theoretic model. By comparing outcomes from both scenarios, we determine the viability of sharing logistic resources for each player.

4 - Price optimization for car sharing

Rym M'Hallah, Christine Currie, Beatriz Brito Oliveira

Car sharing could support the transition toward net zero by reducing private car usage. Its success depends on its financial sustainability to service providers and attractiveness to end users. Dynamic pricing could incentivize users, balance supply and demand, and improve the cost-effectiveness and attractiveness of car sharing. We describe a fast method for optimizing the hourly rental price charged to a car sharing customer where the price may depend on the number of cars already on hire. The usage of the fleet can be described by a continuous time Markov chain model, which can be reduced to a multi-server queueing model under relatively unrestrictive assumptions. The analytical tractability of the queueing model enables fast optimization to maximize expected hourly revenue for either a single fare system or a system in which the fare depends on the number of cars on hire, while accounting for stochasticity in customer arrival times and the durations of hire. This allows for the development of dynamic pricing strategies for car sharing and supports answering more strategic questions such as the optimal fleet size. We present the optimal prices for a given customer population and arrival rate and show how the expected revenue and car availability depend on the arrival rate into the system, the willingness-to-pay distribution, and the size of the customer population. We present the results of experiments showing the optimal fleet size for a given customer population.

1 - A Novel CVRP Model with Simulated Annealing for Fuel Delivery: A Case Study for Clients of Samat Transportation Company in Poland

Vitalii Naumov

The paper addresses the Capacitated Vehicle Routing Problem (CVRP) in the context of fuel delivery to gas stations. The CVRP aims to minimize total travel distance for a fleet with limited capacity. Fuel delivery, however, introduces unique complexities within the CVRP framework. We propose a novel approach that integrates the Simulated Annealing (SA) algorithm with a customized CVRP model specifically designed for gas station networks. This model incorporates real-world constraints like vehicle capacity, fuel demands at each station, and road network distances. The paper outlines the design of the SA-based CVRP model for fuel delivery. We detail the objective function (minimizing distance) and the SA's exploration mechanism for generating candidate solutions. To assess its effectiveness, the proposed approach undergoes computational tests in Poland's gas station network serviced by the Samat transportation company. We compare the performance of our SA-based CVRP model with the conventional Integer Programming model for CVRP powered by Gurobi. The results aim to demonstrate the efficacy of SA in finding efficient fuel delivery routes, potentially leading to cost reductions and a lower environmental impact for transportation companies.

2 - Inventory Routing Problem: A New Integrated Clustering and Routing Algorithm

Okan Ozener, Ali Ekici

Inventory Routing Problem (IRP) arises from vendor-managed inventory business settings where the supplier is responsible for replenishing the inventories of its customers over a planning horizon. In the IRP, the supplier makes the routing and inventory decisions together to improve the overall performance of the system. More specifically, the supplier decides (i) when to replenish each customer, (ii) how much to deliver to each customer, and (iii) how to route delivery vehicles between the depot and the customers. In our setting, the supplier's goal is to minimize total transportation cost over a planning horizon while avoiding stock-outs at the customer locations. We assume that the supplier has a fleet of homogeneous capacitated delivery vehicles and abundant availability of the product to be delivered to the customers. Each customer has a constant demand/consumption rate and limited storage capacity to keep inventory. In order to address this problem, we propose a novel integrated clustering and routing algorithm. In the clustering phase, we partition the customer set into clusters such that a single vehicle serves each cluster. In the routing phase, we develop the delivery schedule for each cluster. The novelty of the proposed approach is that it takes the three main decisions (when to deliver, how much to deliver and how to route) into account when partitioning the customer set into clusters.

3 - Key performance indicators for consistent vehicle routing problem

Guillermo Bianchi, Hernán Lespay

We proposed a mixed-integer linear programming (MILP) for the consistent vehicle routing problem with time windows (ConVRPTW), which is solved with a Tabu Search metaheuristic. This study is motivated by the necessity of increasing the service level of companies in the logistics area. The study considers a schedule of routes in multiple periods, where the set of clients and their demand fluctuates in the planning horizon. The objective is to minimize the length of routes

fulfilling the requirements of service consistency. The solution is evaluated through Key Performance Indicators (KPIs) to analyze the balance between routes, design strategies to perform routing plans, and improve future benchmarks in the literature.

4 - On combining conventional door-to-door and pneumatic waste collection systems

Maryam DehghanChenary, Richard Hartl, Stefan Irnich, Christian Tilk

The increasing global emphasis on sustainable waste management has stimulated efforts to refine transportation infrastructure and travel regulations to improve the efficiency of garbage collection as a pivotal element within sustainable urban municipal solid waste management strategies. Therefore, improving waste collection systems can lead to various enhancements in quality of life. The most common waste collection form is the Door-To-Door Collection System, where household waste is picked up using trucks or other vehicles. Some disadvantages of this system are using trucks on narrow streets, hygienic effects, and malodor related to waste storage. An alternative method is the use of automated waste collection systems.

This study focuses on developing a system that integrates a stationary pneumatic waste collection system with a door-to-door waste collection system. In this fashion, We provide a mathematical model for this combined waste management system with the goal of minimizing total transportation costs. We present a holistic solution approach based on a set-partitioning formulation utilizing vehicle routing problems and price-collecting Steiner tree problems.

Location of Alternative Fuel and Charging Stations

Stream: Locational Analysis

Invited session

Chair: Ozgur Araz

1 - Strategic Locations of EV Charging Stations: Catering to Various Charging Types and Diverse Driver Profiles

Jingyu Xiang, Paula Carroll, Annunziata Esposito Amideo

As a promising sustainable transportation solution, Electric Vehicles (EVs) require efficient strategies for their refueling to complete their journey. This study aims to address the charging station location problem (CSLP), considering multiple charging options and varied driver behaviours. We first integrate the Multi-Path Refueling Location Model (MPRLM) with various charging types, including slow, fast, and battery-swapping charging stations. This model considers different charging rates of multiple charging stations, assuming a linear recharging rate over time. To balance the investment cost of charging stations and the service level for EV users, our objective involves minimizing the total cost for operators and the overall charging time for EV users. Experimental tests on a 25-node network indicate the extended MPRLM outperforms the original model by better balancing system costs, charging time, and station utilization. Then, the Integrated Behavioral Multipath Refueling Location Model (IB-MPRLM) is introduced to incorporate varied charging profiles of EV users. We categorize private EV drivers based on their sensitivity levels to range anxiety, charging costs, and charging time. For each EV driver category, the satisfaction function and satisfaction threshold are established. In this IB-MPRLM, the charging station located at a certain node can only refuel an EV when the user's satisfaction is higher than the threshold of the EV user.

2 - Locating Fuelling Stations for Zero-Emission Aquaculture Vessels

Sarka Stadlerova, Peter Schütz, Robin Halseth Aakvik, Kenneth André Inghelm Mørkved

The aquaculture industry contributes considerably to CO2 pollution in Norway, whereas about 40% of the aquaculture sector emissions are caused by aquaculture vessels. The aquaculture industry is expected to grow in the coming years. However, emissions must be reduced by 55% by 2030 to meet the goals set in the Paris Agreement. Therefore, it is critical to decarbonize the aquaculture operations. The transition of the aquaculture vessels to zero-emission energy carriers such as hydrogen is a promising solution. However, the adoption of hydrogen solutions is hindered by non-existing hydrogen infrastructure.

To address this challenge, we formulate a location routing problem, considering the location of hydrogen fuelling stations and the routing of aquaculture vessels. The aim is to decide the location of fuelling stations, which routes to serve, and the number of necessary vessels to satisfy demand. The objective is to locate hydrogen fuelling stations so that opening costs of fuelling stations, vessel costs and routing costs are minimized. We solve the problem using a path flow model formulation with a priori route generation.

Our case study is inspired by the real case from Norway considering a location routing problem of well-boats in Lofoten and Vesterålen.

3 - Locating Electric Vehicle Charging Stations and Environmental Justice

Ozgur Araz, Ibrahim Capar, Tammy Beck

Recently, improving the infrastructure for Electric vehicles (EVs) has been a major focus of organizations around the world. In this study, we present a service network design framework to improve the infrastructure for EVs with quality-of-service constraints taken into consideration. We present a novel charging station location model with capacity allocation, and we consider the community impact in locating these stations. First, we present descriptive analysis of community impact of charging stations in the United States. Then, we highlight how charging times at stations affect the quality of service in the whole service system by quantifying the improvements in flow coverage while reducing waiting times, in addition to maximizing the community impact. The value of faster chargers in increasing coverage and reducing the average waiting times is also highlighted in relation to a service provider's budget constraints.

Container Stacking and Yard Planning I

Stream: OR in Port Operations

Invited session

Chair: Christopher Expósito Izquierdo

1 - Partial container premarshalling approaches using constraint programming

Celia Jiménez-Piqueras, Dario Pacino

The premarshalling problem aims to rearrange the containers in a port yard bay, comprising a set of adjacent stacks, to prevent containers from being placed above others that must be retrieved earlier. This arrangement streamlines retrieval from the bay for transfers to inland or maritime transport, as additional relocations are avoided at the time of retrieval. Premarshalling is only performed during crane idle times, and the original formulation of the problem assumes these times are unlimited. However, constraints in practice may limit the time available, hindering full bay arrangement. In such cases, partial premarshalling can still enhance retrieval efficiency within time constraints, but existing formulations for complete premarshalling lack adaptation for partial solutions, yielding suboptimal outcomes. Furthermore, while the goal of premarshalling is clear, to achieve a fully arranged bay, various objectives for partial premarshalling can be pursued. This study explores different criteria for partial premarshalling and investigates several constraint programming-based solution approaches.

2 - A Target-oriented Robust Optimization Approach for Vehicle Positioning and Scheduling Problem at Terminal Apron

Linfei Guan, Chenhao Zhou, Qinghe Sun, Ada Che

The container terminal comprises two modules: the yard and the terminal apron, where vehicles engaged in loading/discharging operations are shuttled between the two modules using holding buffers to mitigate congestion and delays. However, uncertainties such as container retrieval locations in the yard, vehicle speed, and potential waiting times due to congestion or incidents, introduce unpredictability in container transit time and may lead to delayed arrivals at the terminal apron. This unpredictability presents challenges in estimating the makspan for handling vessels, particularly for loading operations. This study addresses the integrated optimization of vehicle positioning and scheduling problem at the terminal apron, considering uncertain transit times. The research aims to enhance the tolerance of the terminal apron system to delays in the completion of loading operations in an uncertain environment, striving to develop an efficient and robust vehicle scheduling plan. Stochastic programming is utilized to model the ambiguous transit times, and a target-oriented robust optimization (RO) model is introduced to maximize the system's tolerance to delays. Three approaches are utilized to address the RO, and the performance RO is evaluated across four dimensions: mean, standard deviation, target completion probability, and value at risk. Finally, the RO exhibited strong performance in numerical experiments constructed using real data in Tianjin Port in China.

3 - A new modeling approach for the unrestricted block relocation problem

Fabian Wilschewski, Alf Kimms

We consider the block relocation problem (BRP), a combinatorial optimization problem that may arise in storage systems where items are organized in stacks. The objective is to retrieve all items in a predefined order with a minimal number of relocations. It can be distinguished between a restricted and an unrestricted version of the BRP. While in the restricted BRP (R-BRP) only relocations of items located above the item to be retrieved next are permitted, in the unrestricted BRP (U-BRP) all possible relocations are allowed. Existing exact methods concerning the BRP are frequently search-based methods which appear to be very effective. Nevertheless, recent literature concerning the R-BRP has shown that model-based methods can be competitive and therefore should also be taken into consideration. In this paper, we propose a new model-based approach for the U-BRP. It eliminates the fact that the number of variables is increasing with the number of necessary relocations; a disadvantage most mathematical models for the U-BRP have in common.

1 - Well-being horizons for silver and golden ages: An application of traditional and fuzzy Markov chains

Qi Guo, Irene Albarran, Pablo Jesús Alonso-González, Aurea Grané

European societies are currently in a process of population ageing. Although this is the general trend, it would be desirable to know whether this process is being produced with the same characteristics and intensity in all European countries. In this work information from the last three waves of SHARE macro-survey is used for four countries

(Germany, Poland, Denmark and Spain) as the basis for a longitudinal well-being and dependency indicator with the aim of studying whether the characteristics of ageing are similar in these regions. First, long-term population distributions are obtained according to the value of the aforementioned indicator. Next, classical and fuzzy Markov chains are used to obtain steady-state distributions regarding age group, gender, country and wave. Finally, a proper metric for probability distributions is used to cluster these profiles in several groups. Results lead us to conclude that the ageing process is not homogeneous among the studied populations.

2 - A beta binomial approach for the estimate of surrender rates by GAMLSS

Davide Biancalana, Fabio Baione

This study examines the estimate of surrender probabilities with explanatory variables using a Beta Binomial Generalized Linear Model for Location, Scale, and Shape (BBGAMLSS) and introduces an algorithm for the update of surrender probabilities by future observations. The Binomial Generalized linear Model is widely used in actuarial practice and literature to predict surrender probabilities per policy count depending on the policy, policyholder, and economic variables. We propose an alternative regressive model with a response variable assumed to be Beta Binomial. In contrast to a binomial, a discrete random variable called a Beta Binomial has a beta distributed probability of success at each of a certain number of trials rather than a fixed probability. The surrender is a binomial phenomenon where the probability of success is not fixed, because it depends on many variables that cannot be considered simultaneously in a single regressive model, without introducing overparametrization. Lastly, the Beta Binomial random variable has a Bayesian interpretation, because the beta is a conjugate prior to the Beta Binomial. Then, it is possible to define an algorithm that allows updating the estimates of conditional surrender probabilities by the future observations of surrender rates avoiding the estimate of new parameters every year.

3 - Utility based evaluation of Reverse Mortgages

Gabriella Piscopo

The reverse mortgage (RM) contract allows elder homeowners to borrow money using their home as security for the loan maintaining the right to live in the house. The debt is repaid by the heirs when the borrower moves out or dies. This contract can constitute a valid support for the spending needs that may arise during retirement. The paper deals with a decision problem of a homeowner who is approaching old age and has to evaluate contracting a Reverse Mortgage or not. We built elders lifetime utility functions considering consumptions, bequest motivations and lifespan uncertainty and solve the maximization problem to find the optimal allocation of the wealth between housing/nonhousing, consumptions and bequest with and without RM. Through our analysis, we expect to find that, in presence of long-term care expenses and house maintenance costs, individual's liquid wealth significantly increase with reverse mortgage. Moreover, homeowner with a higher bequest motivation may have lower utility gains from contracting RM plan as well as individuals with a lower house value respect to liquid assets.

4 - Sustainability risks affecting solvency ratios for insurance companies

Susanna Levantesi, Rita D'Ecclesia, Alessandro Dorazio, Kevyn Stefanelli

This article presents an empirical investigation into the influence of Environmental, Social, and Governance (ESG) scores on the solvency ratio of insurance companies, employing a panel regression approach. By analysing an extensive sample of worldwide insurance companies, our study aims to provide a clear and detailed perspective on the dynamic relationships between ESG performance and the financial robustness of firms in the insurance sector. The results obtained through panel regression will offer crucial insights into understanding how ESG variables may affect the solvency ratio, contributing to the growing literature on financial stability and social responsibility within the insurance industry. This research endeavours to provide valuable information for industry stakeholders, regulators, and investors interested in understanding the impact of sustainable practices on the solvency level of insurance companies.

1 - On-Time Meal Delivery Assisted by Drone Resupply

Wenqian Liu, Lindong Liu, Xiangtong Qi

With the competition between online meal delivery services growing, on-time delivery has become a crucial target for meal delivery platforms to pursue, thus calling for new technologies and operational models. Echoing such a need, we propose a drone resupply approach for meal delivery, where drones transport meals from restaurants to riders en route, and then riders deliver these meals to customers. This model involves the coordination of multiple trucks, drones, and depots, as well as the joint optimization of rider routing and drone scheduling. Our two-phase algorithm solves the problem by first identifying feasible rider routes along with the respective drone schedule for serving order bundles, and second, selecting rider routes using a set covering model. To address the issue of long service periods, we propose a rolling horizon strategy to solve it dynamically. Extensive computational studies are conducted to evaluate the efficiency of the solution method and the effectiveness of the drone-assisted delivery system. The results demonstrate that adopting drone resupply in meal delivery is more efficient than the traditional rider-only mode for maintaining the target on-time service level in large service areas.

2 - Parcel Consolidation In Last Mile Delivery by Vehicle and Drone

Semih Boz, Ahmed Ghoniem, Amro El-Adle

We study parcel consolidation within the context of last-mile delivery, employing both a vehicle and a companion drone to efficiently serve customers across multiple time periods. We present a mixed-integer program and an optimization-based heuristic to address large-scale instances. The efficacy of our methodology is assessed through computational experiments on randomly generated instances, focusing on a residential network in Amherst, Massachusetts.

3 - Robots at Your Service: Covering the Last-Mile in Omnichannel Retail by Robot

Tobias Huf, Manuel Ostermeier

The increasing number of home deliveries paired with various delivery modes and channels require retailers to establish omnichannel networks, integrating stores for direct customer deliveries. This enables versatile shopping opportunities but also increases logistic complexity. The innovative truck-and-robot concept poses an alternative to address the resulting challenges. The concept relies on robots carried and released by trucks to serve customers in predefined time windows. We extend this concept by integrating stores and corresponding customer requests for direct supply from stores, resulting in a new concept that offers robots as a service to pick up and deliver goods to the customers. The problem described is formalized as the Truck-and-Robot Pickup-and-Delivery Problem (TnR-PDP) and solved using a tailored solution approach, the Adaptive Genetic Algorithm (AGA). The AGA is based on a recombination-based search framework but tailored to the problem-specifics (e.g., no or multiple visits per location) using specialized recombination operators and an adaptive search strategy for location and operator selection. Our numerical experiments show that our algorithm works efficiently, outperforming existing benchmark approaches concerning runtime by up to 83%, while improving the solution quality on benchmark instances. Furthermore, an in-depth analysis regarding store integration is applied to provide managerial insights and highlight the benefits of the proposed concept.

1 - Optimal is the enemy of good: Solving very large scale virtual machine placement problems at Amazon Elastic Compute Cloud

Rubén Ruiz

A significant portion of the effort within the field of Operations Research is dedicated to the development of intricate ad-hoc algorithms and models tailored for addressing diverse optimization problems. Frequently, the research community exhibits a preference for complexity in the proposed methodologies. Notably, an esteemed characteristic sought in these methods is the incorporation of problem-specific knowledge, enabling the attainment of results that get as close as possible to optimality.

In academic publishing, the pursuit of marginal gains in optimality gaps is a common goal, even at the expense of introducing additional complexity to models or algorithms. While there is consensus that such endeavors contribute to advancements in algorithms and propel the field of Operations Research forward, a frequently underestimated dimension is the practical applicability of these advancements in industrial settings.

Real industrial problems are often messy with imprecise (or numerous) objectives, soft constraints, preferences and a myriad of situations that demand pragmatic approaches. Additionally, these problems undergo rapid evolution with frequent model refinements, occurring often fortnightly. Here, the ongoing painful adaptation of intricate code bases stemming from ad-hoc methods is not the favored choice. In contrast, solvers offer greater flexibility, allowing faster implementation of new constraints through their APIs than altering tailored algorithms. In industrial contexts, the preference lies in flexibility, maintainability, robustness, and reduced operational load, where a modest optimality gap is deemed a minor trade-off.

Moreover, in the realm of large-scale real-world problems, mathematical solvers often prove impractical. It is commonplace to resort to simplifying the problem for solvability. This practice raises a critical question: Is it logical to insist on chasing optimality in solving a simplified problem with a reduced real-world fidelity? Furthermore, real problems entail vast datasets, often including forecasted or approximated input data. Does it make sense to go great lengths to optimally solve a problem when a portion of the input data involves approximations?

In this presentation, I advocate for relinquishing the pursuit of optimality and, instead, embracing heuristic solvers and simplified modeling approaches. Such strategies yield expedient, adaptable, maintainable, and easily implementable models. The discourse will draw upon various examples, spanning classical routing and scheduling problems, culminating in intricate real-world virtual machine placement bin packing problems encountered at Amazon Elastic Compute Cloud (EC2).

1 - Optimal Planning Tool for Agricultural Waste Management in Vietnam (OPT-AWAMA)

Trung Hieu Tran, Thi Thu Ba Nguyen, Thi Hoa Sen Le, Duc Chinh Phung, Hoai Chung Pham, Phuong Le Nguyen, Thi Anh Phuong Huynh

Vietnam's agricultural sectors have rapidly developed to become major contributions to the growth of economy (e.g., in 2019, Vietnam's rice export revenue achieved US\$1.4 billion). Accompanying the development, however, agricultural waste management in Vietnam (i.e., approximately 76 million tons including 45.22 million tons of rice straw, 8.73 million tons of rice husk, 4.04 million tons of sugarcane bagasse, 6.33 million tons of maize by-products, 1 million tons of coffee shell and 10 million tons of vegetable by-products) has become a challenging issue for rural planners due to the lack of an efficient planning tool and impacts of climate change. As a result, it has increasingly caused air and water pollution in many rural areas of the country. In this project, we thus collaborated with Vietnam institutions (including Hue University of Agriculture and Forestry, Institute of Meteorology, Hydrology and Climate Change, and Transport and Development Strategy Institute) to develop a proof-of-concept planning model for rural planners to optimally locate facilities that produce bio-organic fertilizer from waste, and to determine the optimal set of routes for a fleet of vehicles to collect and transport the waste from farms to facilities. In the novel location-assignment-routing problem, we investigated unreliability in facility location and vehicle routing planning due to the risk of disruptions to location sites and roads (i.e., unexpected failure of location sites and roads due to flood impact). The model aims to minimize total expected cost of locating facilities and routing vehicles under the risk of disruptions (due to flood impact) such that the amount of waste at farms is totally collected. A robust mixed-integer nonlinear programming model for this problem was formulated. The model was further generalised to a multi-period planning problem given limited periodic budgets of locating facilities and deploying vehicles. The model was linearized so that it can be solved using a general-purpose solver. In addition, a meta-heuristic algorithm was developed to solve the large-scale instances within a reasonable computation time. Finally, the model was applied for agricultural waste management in Quang Tri province, Vietnam.

2 - Renault Group Packaging Return Logistics in Europe

Louis Bouvier, Thaddeus Leonard, Guillaume Dalle, Axel Parmentier

This project emerged from a collaboration between the CERMICS laboratory and Renault Group. Their challenge: optimizing reverse empty-packaging logistics for car parts transportation from suppliers to plants. Spanning an entire continent, this multi-attribute inventory routing problem (IRP) involves 30 commodities, 16 depots, and 600 customers—far surpassing existing literature instances. Traditional IRP algorithms do not scale, so we propose a large neighborhood search (LNS). Our approach involves three key steps: (1) generalizing split delivery vehicle routing and IRP neighborhoods, (2) adapting a matheuristic for medium-scale IRP into a large neighborhood, and (3) introducing novel perturbations like customer and commodity reinsertion. Additionally, we establish a new lower bound based on flow relaxation. To foster large-scale IRP research, we release an industrial instance library and open-source our code. Rigorous numerical experiments validate the effectiveness of each LNS component. The industrialization of our LNS, coupled with robust change management, has yielded substantial benefits. At Renault, we have achieved

a 4–5% reduction in packaging logistics costs per vehicle produced, a 50% decrease in packaging shortages at suppliers, and a 10% reduction in CO2 equivalent transport emissions for 2023. These gains translate to millions of euros saved and kilotons of emissions reduced annually.

3 - OCP Optimizes Its Supply Chain For Africa and The World

El Mehdi Er Raqabi, Issmail El Hallaoui, Nizar El Hachemi, Francois Soumis, Ahmed Beljadid, Mohammed Ali Bennouna, Nabil Si Hammou, Michel Fender, Anouar Jamali, Hicham Guellaf, Ilyas Rakhis

Operational research specialists at the OCP Group, the Mohammed VI Polytechnic University, and the Polytechnique Montreal operationalized a system optimizing OCP's supply chain downstream activities. The system simultaneously schedules production, inventory, and vessels while ensuring the highest demand fulfillment. Therefore, it has become central to the OCP planning process. Planners use the optimizer's solutions and insights to improve plans in different OCP sites. Initially, the system was a bottleneck, curbing the use of other supply chain management tools. OCP management now credits the system operationalization with providing operational benefits, contributing to over a \$240 million increase in annual turnover.

(Deep) Reinforcement Learning for Combinatorial Optimization 1

Stream: Data Science Meets Optimization
Invited session

Chair: [Yingqian Zhang](#)

Chair: [Kevin Tierney](#)

1 - PPSTOW: An End-to-End Deep Reinforcement Learning Model for Master Stowage Planning on Container Vessels

Jaike van Twiller, Djordje Grbic, Rune Jensen

Efficient supply chains are vital for both the worldwide economy and environmental sustainability. Container shipping plays a key role in this, known for being an eco-friendly mode of transport. Liner shipping companies are actively working to improve operational efficiency through stowage planning. Due to many combinatorial aspects, some of which are NP-hard, stowage planning is a challenging problem in its representative form. Even though stowage planning can be decomposed into master and slot planning, the subproblems remain challenging. As a result, we are searching for scalable algorithms to solve the stowage planning problem.

In this work, we propose Proximal Policy optimization for master STOWage planning (PPSTOW), a deep reinforcement learning approach to address master planning with focus on global problem objectives and constraints. The experiments show the effectiveness of PPSTOW, as the framework efficiently finds near-optimal solutions for simulated problem instances with realistic vessel sizes and practical planning horizons. In the future, we aim to refine the representativeness of our approach by integrating revenue management, as well as local problem objectives and constraints.

2 - A Tale of Middle-Mile Logistics, Graph Neural Networks, and Reinforcement Learning

Thibaut Cuvelier, Onno Eberhard, Bruno De Backer

Middle-mile logistics describes the problem of routing shipments through a network of hubs while respecting deadlines upon arrival. We consider that the hubs are linked by predefined lines, to which we have to assign vehicles. A very challenging aspect of the problem comes from the finite capacity of the vehicles: allocating a shipment to a given vehicle might block another one from using the same vehicle.

Typical exact solution methods, based on a multicommodity-flow formulation, scale poorly with the problem size and real-world instances become quickly intractable. Instead, we turn to reinforcement learning (RL) by rephrasing the middle-mile problem as a multi-objective Markov decision process, where the state is a graph: the lines (edges) between the hubs and the parcels (nodes). At each round, we assign one shipment to a vehicle or decide that it stays in the same hub. The key ingredients of our proposed method are the extraction of small feature graphs from the state and the combination of graph neural networks (GNN) with model-free RL.

We use the PPO (proximal policy optimization) algorithm, which maintains both an actor and a critic, while being able to cope with a varying number of actions depending on the state. We compare linear functions and GraphNet (a particular kind of GNN) to approximate the policy and value functions. GNNs can deliver up to 40% more shipments than a linear function and both approaches scale well with the number of shipments per truck.

3 - Addressing Real-World Side Constraints in Combinatorial Optimization with Deep Reinforcement Learning

Nayeli Gast Zepeda, Kevin Tierney, André Hottung

Deep Reinforcement Learning (DRL) methodologies have garnered increasing attention in addressing combinatorial optimization challenges, particularly in domains such as routing and scheduling. While recent approaches have demonstrated notable efficacy, especially in classic problems like the Traveling Salesman Problem (TSP) and Capacitated Vehicle Routing Problem (CVRP), they often operate within simplified problem settings, lacking real-world side constraints. Consequently, DRL methods encounter difficulties in generating feasible solutions for more complex scenarios. In this study, we address these limitations by introducing additional real-world side constraints and exploring diverse mechanisms to accommodate them while steering the search towards feasible solutions. Our experimentation extends to a variety of combinatorial optimization problems, including the Capacitated Vehicle Routing Problem with Time Windows (CVRPTW) and Skill-VRP, showcasing our approach's effectiveness in handling practical constraints.

4 - Learning Efficient and Fair Policies for Collaborative Human-Robot Order Picking

Igor Smit, Zaharah Bukhsh, Yingqian Zhang

In collaborative human-robot order picking systems, human pickers and Autonomous Mobile Robots (AMRs) travel independently through a warehouse and meet at pick locations where pickers load items onto the AMRs. In this paper, we consider an optimization problem in such systems where we allocate pickers to AMRs in a stochastic environment. We propose a novel multi-objective deep reinforcement learning (DRL) approach to learn good allocation policies to maximize pick efficiency while also aiming to improve workload fairness amongst human pickers. In our approach, we model the warehouse states using a graph, and define a network architecture that captures regional information and extracts information from efficiency and workload features effectively. We develop a discrete-event simulation model, which we use to train and evaluate the proposed DRL approach. In the experiments, we demonstrate that our approach can find non-dominated policy sets that outline good trade-offs between fairness and efficiency. The trained policies outperform the benchmarks in terms of efficiency and fairness, and moreover, they show good transferability properties when being tested with different scenarios in different sizes of the warehouse.

Monday, 12:30-14:00 - Room: 1001 (building: 202)

New Trends in Generative Adversarial Networks and Deep Neural Networks

Stream: Recent Advancements in AI

Invited session

Chair: Duygu Üçüncü

1 - SDP Relaxations for Training ReLU Activation Neural Networks

Karthik Prakhya, Tolga Birdal, Alp Yurtsever

Solving non-convex optimization problems is crucial for training machine learning models, including neural networks. However, non-convexity often leads to less reliable and less robust neural networks with unclear inner workings. While convex formulations have been used for verifying neural network robustness, their application to training neural networks remains relatively unexplored. In this work, we propose a semidefinite programming relaxation for training two-layer ReLU networks in a lifted space, which can be solved in polynomial time. Numerical experiments demonstrate that this SDP formulation provides reasonably tight lower bounds on the training objective across various prediction and classification tasks.

2 - A new implementation with combining mixture of U-Net and ResNet type architectures for image-to-image translation

Erkut Arican, Khaled Al Hariri

Image-to-Image translation is an area of computer vision that has become popular recently, with various studies providing different implementations. By using Image-to-Image translation with a large dataset, we can create different versions of the same image, and each version will allow us to see how the image looks in a different type of scene. This study aims to explore this field and provide a new implementation that could provide new insight into how images can be transformed. A famous image-to-image translation project inspires our implementation, which has a different generator architecture and normalization method. The implementation utilizes a Conditional Generative Adversarial Network, which consists of a generator and a discriminator. We have used a mixture of the U-Net architecture and the ResNet type architecture for the generator instead of only using a U-Net architecture. For the discriminator, we have used the PatchGAN architecture, which separates the image into different patches and classifies each patch of the image as either real or fake. Generated images are evaluated manually, and the calculated Structural Similarity Index is planned to be used in an automated evaluation system. We plan to continue improving our output and evaluate our results in other ways.

3 - Generative AI Governance by Blockchain Technology

Swati Sachan, Vinicius Dezem, Dale Fickett

Generative AI tools powered by Large Language Models (LLMs) have demonstrated advanced capabilities in generating and articulating coherent textual content closer to the practitioners in domains such as law and finance. Globally, firms have raised ethical concerns regarding LLM's ability to mimic human reasoning, accountability for erroneous outcomes, and the security and privacy of confidential data sent by the prompt of Generative AI. This research aims to find a balance between the responsible application of Generative AI and maintaining human oversight over the generated content by utilizing the inherent immutability and decentralization characteristics of blockchain technology. The proposed blockchain-based auditing system detects unauthorized alterations of data repositories containing ex-ante decisions by an AI decision-support system and automated textual explanations by Generative AI tools. The auditing algorithm compares the unique signature, known as Merkle roots of files stored off-chain (outside blockchain), with their immutable blockchain counterpart. Automated auditing by blockchain promotes the ethical use of AI technologies and

minimizes the risk of discrepancies in attributing accountability for adverse decisions. A case study on pre-litigation tort liability legal cases is presented to demonstrate the practical application.

Cutting and Packing 3 - 3D loading

Stream: Cutting and Packing (ESICUP)

Invited session

Chair: Célia Paquay

1 - Solving a 3D-Bin-Packing-Problem with Deep Reinforcement Learning

Hendrik Jon Schmidt, Dennis Maecker

The 3D Bin-Packing-Problem (3D-BPP) is an NP-hard problem that is particularly important in Operations Research whenever a load must be placed on a carrier. This problem has been studied for a long time from a heuristic perspective in the area of container and pallet loading. Recently, Deep Reinforcement Learning (DRL) methods have been applied to solve 3D-BPPs. These methods show improved performance in decreasing the inference time for generating solutions while their generated solutions can outperform those generated by heuristics. However, the research has paid little attention to generating loading patterns subject to stability constraints, which are relevant for making the generated solutions applicable in real-world settings. This paper develops a DRL algorithm based on Proximal Policy Optimisation to explore whether DRL methods can be used to generate stable loading patterns for placing parcels on a Euro-pallet. Only the offline 3D-BPP is considered. The DRL algorithm is combined with a physical simulation of the generated loading pattern to ensure the load's stability. The algorithm is evaluated based on the recently introduced BED-Benchmark dataset of realistic orders. The evaluation shows that the developed DRL algorithm, on its own, struggles to find suitable solutions for stably placing parcels on a pallet. One reason for this might be the large action space for placing any parcel. This issue could be addressed by combining the algorithm with heuristic solvers.

2 - A Digital Twin-driven approach for the mixed load palletizing problem.

António Ramos, Pedro Rocha, Fábio Moreira, Manuel Lopes

The problem of preparing mixed pallets is one of the main challenges in automating tasks in distribution centers. Whether it's the intrinsic complexity of packaging problems or the need to incorporate physical constraints such as stability and interference between cargo and robots in solving methods, traditional approaches to the problem tend to fall short of real-world needs. In this work we propose an approach based on Digital Twins. A Digital Twin is a dynamic virtual representation of a physical object or system that uses real-world data, simulation models and/or machine learning. The framework of our Digital Twin is based on three main components: classic optimization tools; physics engines; and machine learning. A physics engine is a software system that simulates Newtonian physics in a simulated environment, including collision detection, rigid body dynamics and soft body dynamics. In our Digital Twin framework, packing solutions are generated using classical optimization tools, the physical behavior of which is then simulated in the physics engine. Both results feed the machine learning model so that it acquires the knowledge needed to build solutions that can be used in the real world.

3 - Evaluating stability and efficiency: insights from incorporating static stability constraints in online 3D packing heuristics

Sara Ali, António Ramos, José Fernando Oliveira

Static stability is one of the most important packing requirements, preventing items from collapsing and preserving the safety of operators and cargo during loading/unloading operations. This constraint has often been oversimplified in existing online 3D heuristics, limiting their practicability in real-world settings. Given the diverse impacts of different static stability constraints on solution quality, we embedded four constraints, i.e., full-base, partial-base, and two polygon-based constraints, into online heuristics. The impact of constraints on the heuristics' efficiency regarding bin volume utilization is analyzed on a real dataset. Moreover, the static stabilities of packing layouts in all solutions obtained under four constraints are benchmarked using the static mechanical equilibrium (SME). The SME approach offers a necessary and sufficient condition for cargo stability, yet its application proves to be very time-consuming and impractical in the online context, leading us to use it as a benchmark. The results showed that a high percentage of items (i.e., over 87%) are statically stable under all constraints. The findings also indicate a trade-off between increasing items' stability and increasing the bins' volume utilization. This study offered valuable insights for practitioners in selecting appropriate static stability based on their preferences in prioritizing item stability or efficient bins' volume utilization.

4 - A GRASP for the three-dimensional loading vehicle routing problem with split pickup and time windows under real-time disruptions

Emeline Leloup, José Fernando Oliveira, Célia Paquay, Thierry Pironet

Logistics service providers (LSPs) have to respond to the growing demand from their customers, who offer increasingly widespread e-commerce services. This work focuses on pickup operations, meaning that, real-time changes, such as the arrival of new customers, can be accommodated as the vehicle is initially empty and progressively filled up.

The problem under study is a vehicle routing problem with split pickup, time windows and three-dimensional loading constraints, namely, geometric, vertical stability, orientation, and multi-load constraints.

Throughout the day, the LSP is likely to face real-time changes, called disruptions, and needs to quickly adapt his ongoing routes to accommodate as many disruptions as possible while minimizing costs. We will present a greedy randomized adaptive search procedure (GRASP) to deal with two types of disruptions: the arrival of a new customer and the addition of boxes to a planned customer request.

Applications of knowledge and innovation in finance

Stream: AI & Innovation in Sustainable Finance

Invited session

Chair: Januj Juneja

Chair: Apostolos Mouzakitis

1 - The role of timing in the firm's decision to grow internally or by acquisition

Januj Juneja

We investigate patterns in the optimal timing of the firm's strategic decision for growth internally or by acquisition. Using tools from spectral analysis, and based upon the Fourier series, we devise an algorithm that monitors the timing of key firm policy decisions. We apply this algorithm to the firm's decision to invest in three intangible assets related to the firm's organization capital for the purpose of generating financial performance. We assess it using five measures and through the construction of three hypotheses tied to the time horizon for the return on

each investment, its effect on the capacity in the industry and economy, and the degree to which each form of investment is dependent upon the capital market for its mode of financing. Our results imply that there is variation in the timing of each form of investment and interpret that this variation owes to it taking longer for managers to realize gains when investments are made through mergers and acquisitions relative to internal growth. Managers experience an effect delay in this realization owing to delays in the procurement and application of intangible investments obtained from mergers and acquisitions that require transfer of technical expertise whereas the smaller effect delay for internal growth reflects the faster ability of knowledge-based firms to turn the knowledge already contained in-house into financial performance outcomes. Suggestions for future research are provided.

2 - First- and third-party complementary apps: R&D investment, launching, and M&A strategies

Priel Levy, Tatyana Chernonog

With the massive growth of app usage and smartphone penetration, an increasing number of third-party developers are offering their complementary apps aiming to target the massive audience of the leading core apps, and thereby enhance user experience. At the same time, leading developers launch their own complementary apps, which compete with the third-party apps in terms of quality. The effect of the third-party developer on the first-party developer is twofold: On the one hand, the former creates added value for the core app, which translates into additional profit for the first-party developer, generated by the core app. On the other hand, the competition between first- and third-party substitutable apps threatens the first-party developer's profit gained from its own substitutable app. Similarly, the third-party developer rides on the big market of the core app, while its own market share may be eroded due to the competition between the two substitutable apps. In this study, we develop a game-theoretical model of a market consisting of three apps: a core app, and two partially substitutable apps, both of which complement the core app. We investigate the app developers' R&D strategies, and derive conditions for launching their complementary apps. In addition, the core-app developer's M&A strategy is analyzed.

3 - Managerial econophysics unveiled: a comprehensive literature review on the amalgamation of business process management (BPM) and information entropy analysis

Apostolos Mouzakitis, Anastasios Liapakis

This paper explores the fusion of BPM and information entropy analysis. Its objective is threefold: to uncover potential synergies in enhancing organizational efficiency, present novel perspectives about decision-making processes, and introduce a novel scientific sub-field termed Managerial Econophysics. BPM, integrating IT and management, optimizes workflows, reduces costs, and boosts productivity. The review traces BPM's evolution from quality control to its modern manifestations. It addresses challenges like randomness and complexity, proposing entropy analysis to tackle uncertainty. Entropy metrics aid in performance optimization and resource allocation. The synthesis extends to econophysics, linking financial economics with entropy. Notable figures like Popovic and Shannon are discussed, highlighting entropy's role in financial market analysis. The broader scope of econophysics, including social systems, is explored. This paper argues for additional research into the application of econophysics in organizational settings, bridging the gap between economics, management, and physics. It advocates for integrating econophysics and information entropy analysis into managerial science, creating innovative approaches to process management. Just as natural vectors combine to form geometric spaces, diverse scientific disciplines can merge to forge new scientific frontiers. Managerial Econophysics emerges as an epistemological frontier in process management.

New Market Designs & Models for 100% Renewable Power Systems

Stream: Energy Markets

Invited session

Chair: *Silke Johanneiter*

1 - Price formation and intersectoral distributional effects in a fully decarbonized European electricity market

Silke Johanneiter, Niina Heliö, Juha Kiviluoma, Valentin Bertsch

Traditionally, wholesale electricity prices were driven by fossil power plants' fuel costs. Optimising dispatch in five scenarios of fully decarbonised, sector-coupled European power systems, we show how future electricity prices continue to be driven by fuel prices. In contrast to today's market, their impact can also result from opportunity costs of cross-sectoral demand-side technologies. Particularly, we find that electrolyzers become the main price-setting technology in Europe in the presence of a significant domestic hydrogen demand and abundant low-variable-cost electricity generation. Consequently, future electricity prices highly depend on these uncertain parameters. While flexible electricity consumption is able to adapt to varying price levels, investors in solar and wind power are similarly exposed to price risks as inflexible electricity consumers. Therefore, they could mutually benefit from price-mitigating instruments, such as Contracts for Difference. In the hydrogen sector, producers and consumers do not share such a common interest as hydrogen consumers' final energy consumption costs are highly uncertain, but electrolyzers robustly recover their investment costs across all scenarios and countries.

This work has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement no. 864276.

2 - Economic benefits of residential heating and cooling flexibility: consumer and system perspective

Eric Harrison, Topi Rasku, Juha Kiviluoma

Price-based residential demand response (DR) schemes should be planned to enable win-win situations where both the flexible buildings and energy system enjoy economic benefits. Our study modelled the electrically heated Finnish residential building stock, assuming flexible space heating and cooling as well as water heating. We integrated different penetrations of such buildings to a North European energy system model. Two DR schemes were considered: a grid-interactive scheme, in which flexible buildings participated in the minimization of total system costs, and a self-optimizing scheme in which the buildings minimized their own heating/cooling costs based on pre-determined and fixed electricity prices. Annual operational costs of the combined systems were solved as linear optimization problems to assess the cost savings potential from DR.

The results suggest that while flexible consumers often benefited directly from timing their consumption on more inexpensive hours, wide-scale DR penetration can also impact non-flexible consumers by influencing electricity spot prices. In addition, basing wide-spread DR on pre-determined and fixed pricing, such as day-ahead spot prices, may carry risks for the energy system and electricity market if many buildings shift their demand synchronously, causing new demand peaks.

H2020 TradeRES (grant agreement no. 864276)

3 - Assessing market effects of support instruments for renewables: Are they needed and how to design them?

Johannes Kochems, Evelyn Sperber, Christoph Schimeczek, Kristina Nienhaus

Motivation Future energy systems will be dominated by variable Renewable Energy Sources (vRES). Yet, it is unclear if all vRES investments will recover their costs on an energy only market (EoM) and which market designs could promote necessary investments. Thus, the German case study of the TradeRES project [1] aims to assess vRES remuneration needs and policy options.

Methods We use AMIRIS [2, 3] to assess (among others) a scenario with 85% vRES share (S0). We assess a pure EoM and five different support instruments for vRES. These are: a fixed / variable market premium, two-way contracts for difference, capacity premia and a recent proposal from [4] (Financial CfD). All premia are iteratively adjusted so each vRES agent is refinanced. We evaluate cost recovery rates, power market prices, curtailment and other measures of market performance.

Results The data for Scenario S0 shows that EoM income alone is insufficient, as PV and wind operators cannot fully recover their costs. Market-based cost recovery rates vary depending on the support instrument due to the bidding and dispatch behaviour for vRES, resulting in different prices and market incomes. Our findings also indicate a significant sensitivity to the scenario considered, the degree of model-endogenous flexibility sources as well as backup fuel (hydrogen) prices.

Sources [1] <https://traderes.eu/> [2] doi: 10.21105/joss.05041 [3] <https://dlr-ve.gitlab.io/esy/amiris/home/> [4] <http://hdl.handle.net/10419>

4 - The reform of Balancing Markets: Insights from Portugal and Spain

Hugo Algarvio, António Couto, Fernando Lopes, Ana Estanqueiro

The legislation of the European Commission for regulating the European Internal Market of Electricity (EIME) establishes measures for the electricity market harmonization. These measures are designed to encourage the active participation of renewable generation in balancing markets (BMs). RESTrade (Multi-agent Trading of Renewable Production) tool models and enables the simulation of existing secondary and tertiary markets but also simulates improvements to current market designs. These changes, developed within the scope of H2020 TradeRES project (grant agreement no. 864276) are: i) 15-minute trades of reserves and penalty prices, ii) participation of smaller (0.1 MW) aggregated or single players, and iii) separate procurement and bidding of energy and capacity reserves. They are aligned with the EIME legislation. Furthermore, the tool can also compute the imbalance settlement (IS) based on the Portuguese or Spanish mechanisms such as a new approach for computing the dynamic procurement of secondary capacity. This work uses RESTrade to simulate the BMs of Portugal and Spain during 2019, where the weight penalties are around 18.5% and 21.3% of the wholesale market prices. The dynamic procurement increased the usage of its up and down capacities by 12% and 6% in Spain during the period 2019-2022, respectively. The simulation of a new IS mechanism during 2019 in Portugal and Spain, resulted in a reduced penalty of 12.2% and 4.4% of the wholesale prices paid, respectively.

In South Africa, the Department of Health has introduced mobile clinics to improve access to healthcare for rural communities. In this study, we consider the Witzenberg region, where six mobile clinics have been deployed. The aim was to determine routes and schedules to improve the workload balance, fairness, and transportation cost, while ensuring patients get satisfactory care. The problem is modelled in three phases using both primary qualitative data and secondary quantitative data. In phase 1, a multi-vehicle routing problem is formulated to construct feasible daily routes for the mobiles. Phase 2 distributes the daily routes fairly between the mobile clinics to ensure fairness. Finally, in phase 3, a vehicle routing formulation is used to determine a 4-week schedule for each mobile clinic, by using the daily routes obtained during phase 2 as input. Four different service time estimations are used as input, resulting in four different schedules, each with their own advantages and disadvantages, including cost-effectiveness, robustness, fairness, and continuity of care. AHP was then performed with main decision makers to determine their preferred schedule. Final routes and schedules were determined based on model results, AHP results, and final practical input from the decision makers, resulting in an improvement in workload balance, a 23% reduction in total distance travelled and willingness by decision makers to implement the changes.

2 - Allocation-Routing Problem in a Multi-Hospital Home Hospitalization System: A Case Study of a Healthcare Provider in Portugal

Valentina Bonomi, Renata Mansini, Daniel Santos, Maria Lopes, Ana Barbosa-Povo

We study a Multi-Hospital Home Hospitalization Allocation-Routing Problem (MH-HHARP) to provide a useful tool for a healthcare provider in Portugal for evaluating the impact of the opening of a new Home Hospitalization (HH) unit. Given the complexity of HH systems, where specialized nurses and doctors allocate their time between inpatient and outpatient systems, it is critical to efficiently manage their time and workload. For this purpose, we introduce a Mixed-Integer Linear Programming formulation that aims at minimizing routing costs, alongside introducing two other functions: workload balancing among nurses and the minimization of employed doctors. The model is validated using benchmark instances derived from the provider's historical data. Through single-objective resolutions, we provide an economic analysis that assesses the cost implications and the benefits of opening a new HH unit at the variation of objective function. Furthermore, we explore bi-objective problems through an epsilon-constraints method, presenting significant Pareto frontiers to facilitate the provider's decision-making process regarding the trade-offs between different objectives. A TOPSIS analysis is subsequently applied to identify the optimal solution for the provider according to varying objectives weights.

3 - The intra-hospital patient transportation problem with diverse rolling equipment

Angel Ruiz, Vinicius Martins Ton, Jose Eduardo Pecora

Intrahospital patient transportation is a crucial activity to hospital operations that also impacts patients' satisfaction. The problem consists in assigning each of the incoming transport requests to one of the available porters, in such a way that patients arrive to their destination on time, or their lateness is minimized. Some patients (i.e., hospitalized patients) are transported on the bed they occupy, while others (i.e., external patients) require a wheelchair provided by the hospital. Handling different types of transport equipment may require porters to switch equipment between two transport requests. For instance, a porter may have to visit an equipment depot to pickup (drop off) a wheelchair before (after) serving a request which requires it, increasing the total traveled distance, and reducing the availability of porters to answer other requests. To the best of our knowledge, this work is the first modeling and solving this realistic version of the intra-hospital patient transportation problem with various types of rolling equipment. We propose and compare the performance of several approaches (including a mixed integer linear programming model, a constraint programming model, a constructive heuristic, and a local search heuristic) with respect to metrics widely used by hospital managers over a set of instances inspired by a real mid-size hospital. The local search heuristic produced excellent results and proved its suitability to be used in real applications.

4 - Assess the Equity Impacts of different Transportation Modes using Access to Health Facilities for Asthma Patients an Indicator

Mahnoush Minuyee, Merkebe Getachew Demissie, Anne Hicks, Laleh Behjat, Barry O'Sullivan

Asthma exacerbations can occur due to various factors, including exposure to air pollutants generated by economic sectors, like the transportation sector. Here, we investigate the equity performance of different transportation modes using access to health facilities as key equity outcome. Patients with asthma must get to hospitals soon. Asthma, which affected 10% of the Canada's population in 2021, is one of the most prevalent chronic respiratory diseases affecting children in Calgary in Canada. To achieve transportation fairness, our study focuses on the critical component of spatial accessibility to medical facilities for the medical care of pediatric asthma. We intend to shed light on how accessible it is for patients with asthma to get to the closest medical facilities using different transportation modes. We have developed a comprehensive equity analysis framework to measure access to health facilities. It combines coverage and reachability-based methods and utilizes both vertical and horizontal equity techniques. We calculated accessibility metrics at different geographical levels to highlight how various transportation modes impact access to health facilities, such as at the community district or city sector level. Our findings demonstrate that transportation planners can leverage insights generated from both vertical and horizontal equity analyses to enhance transportation services in underserved communities, thereby improving access to various health facilities.

Behavioral Decision Analysis II

Stream: Behavioural OR

Invited session

Chair: Gilberto Montibeller

1 - Time preference influences attribute weights and values in multi-attribute decision-making

Pinel Gulum Tas, Yousef Maknoon, Jafar Rezaei

Eliciting attribute weights and values are two crucial steps in many multi-attribute decision-making (MADM) methods. Due to their high reliance on judgmental inputs from decision-makers, these steps can be subject to various behavioral factors, including time preference. Given the frequent application of MADM methods in many strategic real-life problems, examining time-related behavioral vulnerabilities and providing systematic approaches to overcome them become imperative. This study investigates the time preference phenomenon in complex, multi-attribute decision-making problems. A special experiment is designed following the Multi-Attribute Value Theory (MAVT) steps, and a health-related intertemporal decision problem is used. In a within-subject design, participants' preferences are used to elicit attribute weights and value functions considering different resolution times of a health-related outcome. Data were collected from six European countries via an online platform. The statistical analyses indicate the significant influence of time preference on elicited importance weights and value functions. Subjects assigned different weights to the same attributes and different values to the same outcomes depending on the time of the realization of outcomes. These findings have significant implications for both practitioners and researchers.

2 - Anchoring bias in Multi-Attribute Value Theory

Geqie Sun, Maarten Kroesen, Jafar Rezaei

Anchoring bias, a well-known cognitive bias, occurs when people heavily rely on the initial information they receive, influencing subsequent judgments or decisions. This study examines anchoring bias

in multi-attribute value theory (MAVT), focusing on its impact during value function and weight elicitation process. Hypotheses were formulated to investigate the presence of anchoring bias in MAVT and to explore potential strategies for mitigating its effects. These strategies were derived from the "consider-the-opposite" concept, a recognized de-biasing approach for anchoring bias and were customized to fit the MAVT process. To test the hypotheses, an experimental study was conducted based on a real-life decision-making problem. We created a questionnaire in alignment with the MAVT methodology and collected data via an online platform. The findings indicate that anchoring bias has an impact on both the value function and weight elicitation steps. Additionally, suggested mitigation strategies were observed to be somewhat effective, offering decision-makers practical tools to partially address anchoring bias. In conclusion, this research contributes to enhancing decision-makers' awareness of anchoring bias as well as offering actionable insights for decision-makers aiming for more accurate and unbiased decisions.

3 - Poor choices and post-decision surprises - the impact of evaluation uncertainties in multiattribute decision-making

Eeva Vilkkumaa, Taeyoung Kee, Juuso Liesiö, Pekka Malo

Decisions that involve multiple attributes are commonly supported by decision analysis methods deploying a multi-attribute value/utility function, which captures decision-makers' preferences on multiple decision attributes and their risk attitude. Often, there are uncertainties related to the evaluation of the decision alternatives' attribute-specific performances. In the context of single-attribute problems, these uncertainties cause the ex post realized performances of the selected alternatives to be systematically lower than the ex ante estimates, causing the decision-maker to experience post-decision disappointment. We study the impact of attribute-specific estimation uncertainties and nonlinear utility functions on post-decision surprises and the quality of decision making in a multiattribute setting. In particular, we present both analytical and simulation results to analyze the performance of several selection approaches by examining whether these approaches lead to the optimal choice that maximizes the expected multi-attribute utility and whether these choices correspond to the truly optimal choices that maximize the ex post true multi-attribute utility. Furthermore, we demonstrate the impacts of these selection approaches in a realistic example on choosing a contractor for a construction project.

4 - Behavioral Decision Research: Descriptive and Prescriptive Perspectives

Detlof von Winterfeldt, Gilberto Montibeller

Behavioral Decision Research has provided a deep understanding of how humans form judgments and make choices, since its emergence in the 1950s. Underlying this body of research is the contrast of actual decision making with the paragons of rationality, which provide the idealized model on how humans should decide. Starting with the Ellsberg and Allais paradoxes and followed by Tversky & Kahneman's seminal research, it has been clear that no real person is fully rational. Exploring deviations from rationality has been a major focus of Behavioral Decision Research. This research has two quite distinct branches: descriptive and prescriptive. Descriptive Behavioral Decision Research examines deviations from rationality and strives to develop theories or models to explain these deviations. Prescriptive Behavioral Decision Research also starts from observed deviations from rationality, but rather than developing theories of models to explain these deviations, it develops and tests tools or analytical methods to correct these deviations. The distinction between the descriptive and prescriptive perspectives in Behavioral Decision Research has often been implicit and blurred in the Decision Sciences literature. In this paper we aim to address this conceptual lacuna, proposing a taxonomy for these two perspectives in Behavioral Decision Research and describing their main achievements.

Agrifood supply chain decision problems

Stream: OR in Agriculture and Forestry
Invited session

Chair: Franco Basso

1 - Predicting price fluctuations of commodities by the joint use of extreme value techniques and machine learning methods: a case study of cherry price forecast

Myriam Gaete, Marcela C. Gonzalez-Araya

Predicting export product prices is important for export companies for negotiating contracts with the associated participants of the supply chain. In this study, extreme value techniques are used for normalizing data of price fluctuations, and then, machine learning methods are applied for estimating future price fluctuations. This methodology is applied to a case study for estimating the export price of sweet cherries. The results show low error in the price fluctuations' forecast, with a MSE lower than 1. Besides the good performance, the proposed methodology is easy to implement and can be executed in a low computational time by using personal computers.

2 - A Hybrid Solution Approach to Support Fresh Fruit Supply Chain Cold Storage and Transportation Decisions

Nicolás Reyes, Marcela C. Gonzalez-Araya, Wladimir E. Soto-Silva, Lluís Pla

Planning the cold storage and transport requirements throughout the fresh fruit supply chain is essential for decision makers, in order to preserve fruit quality and reduce fruit loss. This study presents a multi-period mixed integer linear programming (MILP) model for supporting cold storage and transport decisions of the fresh fruit supply chain, aiming to minimize total costs. For solving the proposed model, a hybrid solution method is developed, which combines a constructive heuristic algorithm and an exact method to build solutions incrementally, that is, period by period. A real case study from a Chilean fruit company is used for demonstrating the suitability of the hybrid solution method, which requires much lower computational time than the exact method for finding near optimal solutions (about 0.1% of the time required by the exact method). The results show that the hybrid method finds solutions with gaps in objective function values less than 2.0% compared to the objective function values obtained by the exact method. These results provide more alternatives for planning cold storage and transportation requirements in the fresh fruit supply chain.

3 - Multicommodity Fresh Produce Trade Networks with Quality Deterioration Under Congestion and Transportation Capacities

Deniz Besik, Anna Nagurney

This paper constructs a multicommodity spatial price equilibrium framework designed to allow for the quantification of the impacts of congestion and transportation capacities on trade flows and product prices while capturing the degradation of fresh produce quality through explicit quality deterioration formulas. We present the multicommodity fresh produce trade network model under equilibrium conditions both without and with minimum quality standards. Alternative variational inequality formulations of the governing equilibrium conditions are derived, with one of them exhibiting particularly favorable features for computational purposes. The numerical examples focus on the banana trade, since bananas are the most widely traded fresh produce commodity globally, with leading exporters being Ecuador and Costa Rica and major importers, United States and the European Union. Through various scenarios, we simulate congestion and time delays in the Panama Canal and report on the impacts of ongoing disruptions, on shipment times, equilibrium shipment volumes, the supply and demand prices, quality levels at the supply markets and at the demand markets, and transportation costs. Our baseline numerical example results closely align with real-life data on export volumes of bananas,

the associated supply and demand prices, and transportation costs. The comprehensive numerical results reveal that reductions in transportation capacity and prolonged shipment times, as in the Panama Canal.

4 - A horizontal collaboration approach for grape transportation in a pisco cooperative

Franco Basso

This paper proposes a novel horizontal collaborative framework for grape transportation within a cooperative that supplies grapes for pisco production. Nowadays, each cooperative member collects and delivers grapes to previously assigned processing plants without coordinating with the other members. In order to evaluate the potential impact of shared transport resources, we model collaboration among farmers as a cooperative game with transferable cost, where a mixed integer programming formulation that models transport activities is repeatedly solved for computing the characteristic function. Although the grand coalition is theoretically better than any other coalition structure, our approach limits the number of farmers per coalition to assess incremental collaboration's benefits. By conducting a case study involving sixty farmers, we show that a collaborative approach leads to a 13.4% reduction in the cooperative's transportation costs. However, we observe that the benefits of collaboration show diminishing returns. Particularly, we show that a coalition structure with a maximum number of three players per coalition captures almost 94% of the maximum potential savings.

Approaches for Integrating Quantitative Modelling

Stream: Soft OR and Problem Structuring Methods
Invited session

Chair: Mike Yearworth

Chair: Isabella Lami

1 - Triggering a "Plural Subject" through the software "MuVAM" combining Strategic Choice Approach and Analytic Hierarchy Process

Elena Todella, Isabella Lami

This research intends to investigate, within a decision-making process, the affordances enabled by the use of a specific artifact, a new software called Multi-Values Appraisal Methodology (MuVAM) created on a multi-methodological approach recently introduced in the literature (Lami and Todella, 2023). MuVAM combines the Strategic Choice Approach with the Analytic Hierarchy Process and it is based on cloud-based technologies, which allow synchronized and connected use, digitally and also in asynchronous mode. The study investigates the contribution of the software to group interaction and the development of a "Plural Subject" through the analysis of eight workshops, held in four different European countries, in three languages (English, French and Italian) and on four different case studies, all related to sustainable urban development. In particular, the applications differed with respect to: i) the scale of intervention, ranging from the planning of an entire city area to that of a university campus; ii) the outcome, which in most cases concerned the definition of a master plan. Interestingly, the participants in the workshops were also quite diverse: Bachelor's, Master's, PhD and Lifelong Learning Master's degree students, with a varied experience in terms of educational level and background. Feedback from the workshops was collected through a report or a Google survey, through a series of questions covering both group dynamics and individual choices.

2 - Hierarchical Process Modelling (HPM): integrating conceptual and quantitative modelling

Mike Yearworth

The development of a problem structuring sensibility in engineering has led to a processual turn in engineering practice. By adopting a strong process epistemology - everything can be modelled as a process - it is possible to model purposeful activity conceptually, even if it includes processes that will eventually become reified as objects in the world. In addition to this delayed reification, Hierarchical Process Modelling (HPM) has an inbuilt measurement schema for process performance that includes an explicit representation of uncertainty and the possible calculation of overall performance using necessity and sufficiency conditions. Modelling proceeds from an initially agreed purpose amongst stakeholders through a how/why questioning dialectic in group model building. Since a processual interpretation of engineering practice has been made evident using this modelling approach, it is possible to examine the implications for integrating hard/soft OR practice. These are discussed, supported by case examples.

3 - Empirical and historical explorations of integrating qualitative and quantitative analyses

Eleanor Reynolds

This paper considers how we recognise the impact of qualitative analysis within interventions. First, empirical data is used to illustrate the integration of qualitative and quantitative within the context of an everyday workplace, considering patterns of integration and their perceived effects. Second, the historical basis for valuing the integration of qualitative and quantitative is explored, considering the longer-term evolution and use of Soft OR and Problem Structuring Methods (PSMs). Finally, I reflect upon the broader questions these observations raise about the relevance of qualitative analysis and how we promote this relevance within and beyond our immediate community.

Machine Learning for Electricity Market Applications

Stream: Energy Markets
Invited session

Chair: Lesia Mitridati

Chair: Farzaneh Pourahmadi

1 - Less than meets the eye: simultaneous experiments as a source of algorithmic seeming collusion

Xavier Lambin

This article reassesses the assertions regarding algorithmic collusion presented in Calvano et al. (AER 2020) and subsequent literature. We first reveal an important mistake in the original papers, which refutes the idea that the phenomenon of supracompetitive prices arises from collusive mechanisms where reward and punishment schemes support high prices. Then, our theoretical and simulation-based analysis suggests that both the high prices and the apparent punishment schemes result directly from simultaneous experimentation and the learning inertia inherent in most reinforcement learning techniques. The co-occurrence of high prices and apparent price wars is not causal and both stem from imperfect learning. We demonstrate that such seeming collusion can arise in memoryless environments, even with myopic agents, and much faster than previously thought. Our findings alert on the risk of qualifying as collusion a phenomena that is not, and invite new, simple approaches to address the issue of algorithmic supra-competitive pricing.

2 - Forecast Equilibrium in Electricity Markets

Vladimir Dvorkin

Renewable power producers participating in electricity markets build forecasting models independently, relying on their own data, model and feature preferences. In this paper, we argue that in renewable-dominated markets, such an uncoordinated approach to forecasting results in substantial opportunity costs for stochastic producers and additional operating costs for the power system. As a solution, we introduce Regression Equilibrium—a welfare-optimal state of electricity markets under uncertainty, where profit-seeking stochastic producers do not benefit by unilaterally deviating from their equilibrium forecast models. While the regression equilibrium maximizes the private welfare, i.e., the average profit of stochastic producers across the day-ahead and real-time markets, it also aligns with the socially optimal, least-cost dispatch solution for the system. We base the equilibrium analysis on the theory of variational inequalities, providing results on the existence and uniqueness of regression equilibrium in energy-only markets. We also devise two methods for computing the regression equilibrium: centralized optimization and a decentralized ADMM-based algorithm that preserves the privacy of regression datasets.

3 - Gas Trading with Tariff Versus Sanction as a Networked Game

Frédéric Pokou, Hélène Le Cadre, Marta Fochesato

The economies of many geographic markets are dependent on fossil fuels. Due to geopolitical tensions, some geographic markets may decide to partially or totally halt their gas trades. We therefore propose a model which casts the optimal taxation problem as a networked game in two settings: a) perfect competition, where a global market operator is responsible for adjusting the export prices, leading to a partial equilibrium; b) a variational approach, where the export prices are determined endogenously as dual variables of the supply-demand balances. Our model is built on an agent based representation of suppliers and generators interacting in a certain number of geographic markets. We aim to assess the impact of tariffs or sanctions on the geographic markets' imports of gas and on their utility. To that purpose, the optimal taxation problem is framed as a Stackelberg game where a regulator at the upper level is responsible for the sanction definition considering different criteria, while the geographic market at the lower level reacts by adjusting their exports and trade prices. We derived closed-form expressions for the export prices, and proved that the Stackelberg equilibria can be explicitly mapped to the perfect competition equilibria. Finally, considering a degree of bounded rationality on the part of stakeholders, we rely on Prospect Theory to extend the optimal taxation games to in situations involving risks linked to the behavior of other market stakeholders.

Monday, 12:30-14:00 - Room: 18 (building: 116)

Healthcare Analytics

Stream: OR in Health Services (ORAHs)
Invited session

Chair: Vedat Verter

1 - Leadership Engagement Acceleration & Partnership (LEAP) Digital Health Hub: Driving Sustainable Digital Healthcare

Daniel Gartner, Ian Craddock, Andrew Dowsey, David Ellis, Paul Harper, Hanna Isotalus, Maneesh Kumar, Richard Luxton, Martin Pitt, Christos Vasilakis

The Digital Health Hub, funded by UK's Engineering and Physical Sciences Research Council, is a collaborative initiative in the South West of England and Wales bringing together leading universities, supporting companies, National Health Service Trusts, and social care organizations to create a dynamic ecosystem for training, research, and

collaboration. The hub has three pillars. Firstly, the Hub's Skills and Knowledge Programme responds to the professional training needs of industry, health and social care providers, and academia, focusing on two key themes: Transforming Health and Care Beyond the Hospital, and Optimizing Disease Prediction, Diagnosis, and Intervention. The aim is to develop the necessary skills and expertise to drive innovation and deliver effective digital healthcare solutions. Secondly, the Hub's Fellowship programme nurtures future leaders across academia, industry, health and care sectors, and the wider community. With five different schemes, it offers a platform for aspiring leaders to influence the future of digital health. Finally, the Hub's Research programme focuses on advancing pre-competitive research within the transformative areas of healthcare. By collaborating with organizations, the Hub ensures that research efforts align with current health priorities and add value to the healthcare landscape. Our presentation provides an overview of the '3.2 million three-year programme.

2 - On Reducing Medically Unnecessary Procedures Through Analytics: The Design of Financial Incentives for Maternity Care

Beste Kucukazici, Emily Zhu, Ting Wu

This work focuses on the design of financial incentives to reduce medically unnecessary C-sections, resulting in enhanced birth quality with alleviated economic burden for healthcare payers. To this end, we develop an innovative semi-supervised fuzzy clustering algorithm to classify pregnant women into low- and high-risk groups by analyzing approximately 18 million birth records from US. Our experiments on real-life and synthetic data demonstrate the efficiency of our algorithm for large datasets. Then, we validate the optimal delivery methods for two risk groups through post-delivery outcomes for the mother and the newborn by using inferential statistical analysis. Furthermore, we develop a metric to quantify the maternity risk index to be used in stylized analytical models. Next, we develop an analytical framework based on a principle-agent model to analyze the effect of different payment schemes from the quality of care and cost perspectives. We propose three payment systems, hybrid payment, risk-sharing model, and penalty contracts to alleviate the shortcomings of fee-for-service and bundled payment schemes, thereby facilitating system optimal decisions. Finally, we present a simulation-based numerical study to empirically verify our analytical results.

3 - Data driven exploration and modelling of patient flows through NHS Talking Therapies care pathways

Elizabeth Yardley, Alice Davis, Christos Vasilakis

It is estimated that one in six adults in England have a mental health disorder and would benefit from a course of psychological therapy. The NHS Talking Therapies Programme treats over a million patients with common mental health problems each year according to the principle of stepped care, where effective but less resource intensive treatments are delivered to patients first and higher intensity interventions are then provided if required.

In order to meet NHS targets, the programme will need to increase access rates, while meeting service standards for waiting times and recovery rates. Mental healthcare providers are therefore looking at all opportunities to increase capacity and productivity. The aim of this project is to develop innovative, advanced, analytical tools to help improve understanding and management of NHS Talking Therapies services' demand and capacity.

This study analyses data from iaptus, the leading digital care record for psychological therapy services, to investigate and model patient flows through talking therapy care pathways using process mining and other data-driven methods, augmented by simulation modelling to evaluate pathway performance and explore relationships between performance issues. The major impacts of this project are expected to be improved access to services, improved utilisation of resources, resulting in reduced waiting times, better recovery rates and reduced patient drop out.

4 - Measurement Noise and Judgment Bias in Hypertension Management

Vedat Verter, Manaf Zargoush, Mehmet Gumus

Hypertension is a major public health issue and the most important modifiable risk factor for cardiovascular disease. Effective hypertension management is hindered by (i) the noise in blood pressure (BP) measurements (technology factor) and (ii) the physicians' judgment bias (human factor). The latter refers to the physician's error in inferring the patient's true BP from the measurements. This study investigates the role of these two factors in hypertension management from the perspective of the clinical value of information.

We present an analytical framework with two main modules: a learning module that models how clinical judgments about the patient's underlying BP are made (with and without bias) and an optimization module that models how optimal treatment decisions are made under various learning strategies.

Our results suggest that the value of information concerning the patients' underlying BP depends on (i) the physician's judgment bias and decision flexibility, cardiovascular risk as well as the short-term and long-term BP variability of the patient, and the measurement noise of the device. In addition, among the two types of judgment bias (i.e., under-estimation and over-estimation), the value of information is much higher under the under-estimation bias, where the clinician undervalues the significance of the observed BP in inferring the true underlying BP.

1 - Data-driven decision making for secondary school students under the framework of Sustainable Development Goals

Vanesa Guerrero

The "Data Science Gymkhana" is a yearly activity organized with the aim of promoting critical thinking and the development of the scientific method among secondary school students. It was born in 2020 as one of the activities of the program STEM4Girls developed at Universidad Carlos III de Madrid (Spain) to promote scientific and technological vocations among children and young people and, in particular, girls. The Gymkhana seeks to make visible the importance of data science as a driver of change and social transformation in achieving the Sustainable Development Goals (SDG). Each edition is focused on one SDG and top researchers are invited to give a talk about her work. In this edition an Operational Researcher has been invited in connection to the SDG7: Affordable and clean energy. Students have to analyze a data set related to the selected SDG, solve some riddles and present their analysis in relation to the actions we can make based on data. In this presentation, we describe the activity and discuss some of its outcomes and impact.

2 - The experience of the CQIIA-MatNet center of the University of Bergamo

Francesca Maggioni

In this talk we will present recent experiences of the CQIIA-MatNet center of the University of Bergamo (<https://cqiiia.unibg.it/ricerca/matnet>). MatNet is a center which is focused on teaching of mathematics and its applications and which develops collaborations between universities and schools. We will present the experience of the San Pellegrino Summer School on Mathematics and Artificial Intelligence and the seminars series devoted to high school teachers, organized in collaboration with Mathesis Bergamo under the umbrella of Piano Lauree Scientifiche (PLS).

3 - Teaching Predictive Analytics without Coding

Volker Kraft

Building and understanding powerful Machine Learning algorithms requires statistical thinking supported by accessible and powerful tools. JMP Pro brings advanced predictive modeling into the classroom, without any need for coding.

As teaching examples, automated Model Screening and state-of-the-art Torch Deep Learning will be demonstrated from a student's perspective. We will discuss course use and teaching best practices.

4 - Graduates' Employability and the Digital Transition: Tuning a Problem-Based Approach and Enhancing OR/MS Courses

Joao Miranda, Ana Paula Teixeira

Nowadays, the digital transition and related developments on graduates' employability are key for Higher Education Institutions (HEI), balancing either their fast pace or the impacts multiplicity. For that, a Problem-Based Learning (PBL) approach is revisited and tuned with digital support, in a manner to better promote the OR/MS learns within a Management Science 's graduation program. Specific problems are thus built to promote reasoning, to conjugate both the work context and professional environment, with quantitative approaches and OR/MS methodologies. While addressing typical contents of Decision Aiding/Making, Linear Programming (LP), Integer Programming, and LP special cases, important insights about optimality and uncertainty are treated, and thereafter Forecasting methods are motivated and introduced. In addition, a set of simple problems and study cases is developed in a way to enhance graduates' analytical and digital skills, and the main outcomes are outlined. Finally, further developments in face of the labor market challenges are also discussed.

5 - The ROAR project: How to improve Grade 10-12 interest and motivation in Mathematics through a learning path based on Operations Research

Alice Raffaele, Gabriella Colajanni, Alessandro Gobbi, Marinella Picchi, Eugenia Taranto

Operations Research (OR) is a discipline of applied mathematics usually taught at the university level. Nevertheless, many initiatives have been developed for younger students in the last few years. Starting from these, we designed Ricerca Operativa Applicazioni Reali (ROAR, i.e., Real Applications of Operations Research), a learning path for higher secondary schools relying on active learning and constructionism. ROAR offers examples and problems closely connected with students' everyday lives, balancing mathematical modeling and algorithms. ROAR aims to improve students' interest, motivation, and skills related to STEM by integrating mathematics and computer science through OR. ROAR is composed of three units. The first one, addressed to Grade 10, is dedicated to introducing mathematical modeling, linear programming, and using GeoGebra and Solver. The second unit, for Grade 11, focuses on graph theory and network applications, strengthening modeling skills and the development of heuristic algorithms. Finally, the third unit, for Grade 12, concerns the implementation of mathematical models with PuLP, an open-source Python library. Every teaching unit ends with presenting a final project to tackle in groups. In this talk, we provide an overview of the implementation of ROAR at the scientific high school IIS Antoniotti in Iseo (Brescia, Italy) from March 2021 to January 2023, and we present derived initiatives and available resources.

1 - Evaluating the impact of staffing recommendations in maternity units

Louis Niffoui, Oualid Jouini, Marija Jankovic, Pierre-François Ceccaldi, Guillaume Lamé

Sufficient midwifery staff is crucial to the quality of maternity care. However, the shortage of staff that France has been facing for several decades creates situations of understaffing. In order to determine the optimum number of midwives in a given department, several methods have been presented in the literature, e.g., a 1998 decree that sets out minimum staffing levels, recommendations from scientific societies, or calculation tools like the British BirthRate Plus tool. Yet, we lack evidence on how these models affect quality of care. We observed the operation of a French public hospital maternity and built a discrete-event simulation model using Simul8 software. The simulation model reproduces the structure, staffing schedules and patient characteristics of the maternity. Because it has been shown that one-to-one care (one midwife for one patient) has a positive impact on service indicators such as readmission rates, stillbirth rates and average length of labour, we used the rate of one-to-one care in labor as our main output. We used design of experiment methods to determine the most influent factors in our model. Using this model, we analysed the impact of different staffing recommendations on quality of care measured by the rate of one-to-one care. In the future, the model will be enriched with time-and-motion analysis data to provide more accurate estimates of how much time midwives can really devote to patient care in delivery units.

2 - Effect of timings and frequencies of HCV treatment camps on epidemiological, health and cost outcomes in Indian Punjab

Soham Das, Varun Ramamohan

In this study, we developed an agent-based simulation model for hepatitis C virus (HCV) transmission in the context of Punjab, an Indian state with a high prevalence of the disease. The model incorporated a dynamic cohort, infection spread through all major modes and a previously validated discrete-time Markov chain for disease progression. We experimented the impact of treatment policies varying in frequencies and timings of treatment camps for different uptake rates. For modelling treatment, we used the cure rates and costs of sofosbuvir plus velpatasvir, a type of directly-acting antivirals having high cure rates. In low- and middle-income countries like India, where budget and resources for healthcare are greatly constrained, it is of interest to test whether annual camps are avoidable. Over a ten-year intervention period, we tested the following policies: (1) annual treatment camp (2) a single treatment camp at the beginning of the intervention period (3) a single treatment camp at the end of the intervention period (4) two treatment camps at the end of the fifth and tenth years of the intervention period (5) three treatment camps at the end of the third, sixth and tenth years of the intervention period. For all uptake rates, we found that while treating once at the end is the best to maximize life years, quality-adjusted life years and net monetary benefits, yet the annual treatment camp is the best to minimize costs, HCV spread and active HCV prevalence.

3 - Using large routine health service datasets for modelling

Sally Brailsford, Tracey England

In the past lack of data was often cited as a major challenge in healthcare modelling, but in recent years large electronic datasets have become increasingly available for use in research. This talk discusses the advantages and disadvantages of using such datasets, in particular routine health service data primarily collected for other purposes, compared with collecting prospective data or using the clinical literature. These 'pros and cons' are illustrated by three case studies. The first dates back to the 1990s and concerns screening for diabetic retinopathy; the other two are connected, much more recent, and concern care for older people. All three projects involved large multi-disciplinary teams of researchers. The first project involved the development of a discrete-event simulation model, parameterised using data from the literature. The two related projects involved the development of system dynamics simulation models, both using large routine health service datasets to estimate the model parameters. While access to such data

Monday, 12:30-14:00 - Room: 40 (building: 116)

Simulation models in healthcare

Stream: OR in Health Services (ORAHs)

Invited session

Chair: Sally Brailsford

might seem to be a luxury, compared with the difficulties of obtaining data for the diabetic retinopathy model, deriving the required information from the data was not always straightforward.

4 - An overview of the application of OR methods to alcohol drinking behaviours, and a geographical analysis of alcohol consumption in Wales

Elin Williams, Daniel Gartner, Paul Harper, Geraint Palmer

Alcohol consumption is a recognised public health issue, and it is believed that the resultant harms are rising since the COVID-19 pandemic. Alcohol drinking affects healthcare including the demands of alcohol-attributable diseases; mental health and housing services demands on social care; and demands on the criminal justice system resulting from violent and aggressive behaviours. This talk will present an overview of the application of operational research (OR) methods to model alcohol drinking behaviours, specifically within healthcare, social care, and criminal justice settings. Some OR methods are utilised frequently in alcohol consumption literature, namely agent-based modelling (ABM), Markov models, and network analysis. The recurrence of ABM and network analysis highlight the social component of alcohol consumption. Other methods such as system dynamics are utilised less frequently but could be useful models to include in the literature to gain a whole-system perspective. Alcohol consumption data collected in Wales can be analysed geographically by health board, local authority, and area deprivation, to gain insights into the diverse alcohol drinking patterns reported, and how resultant harms vary geographically and by consumption behaviour. Based on the literature evidence, alcohol consumption and alcohol-related harms data, and collaboration with stakeholders, an initial proposal on how to model alcohol drinking behaviours across the whole system is presented.

1 - Supporting stakeholders' and citizens' participation and inclusion in planning maintenance processes: multidisciplinary testing practices in Piedmont and Liguria

Umberto Mecca, Allegra Alacevich, Michela Cardinali, Laura Fornara, Andrea Longhi, Simone Martino, Manuela Rebaudengo, Andrea Salice

Since the last three years, a multidisciplinary research group of CCR and Politecnico di Torino has been scientifically supporting the activation of a new strategic digital tool aiming at the preservation of Cultural Heritage (CH) across Piedmont and Liguria and pursuing the transition from existing cultural policies. The presented activities are Institutions' support initiatives promoted by Compagnia di San Paolo through two editions of PRIMA, a call for proposals oriented towards the cultural, economic and social sustainability of CH Conservation Plans. Quite experimentally and in addition to the funding activities, capacity building, thematic coaching and networking have been activated, indirectly educating to the importance of collecting, creating, managing and sharing knowledge, particularly on the issues of CH programmed conservation. The sharing of interdisciplinary expertise and local experiences represents an innovation element which, through peer-to-peer comparison and knowledge sharing, promote the activation of collaborative networks and open up to the use of new financial tools for a more aware and sustainable CH management. In order to measure PRIMA social impact, it has built a monitoring system whose first outcomes (growth of skills, interventions sustainability, involvement and participation of all stakeholders and community), allow to

identify planned conservation as one of the most solid and concrete keys to the achievement of UN SDGs in the field of CH.

2 - Parcel Lockers as a Solution to Urban Logistics Challenges: A Stochastic MIO Model Incorporating Customer Utility

Zisis Maleas, Georgia Ayfantopoulou, Josep Maria Salanova Grau

In the modern urban environment, the rise of e-commerce has led to significant last-mile delivery challenges, notably increasing congestion and air pollution. Estimates suggest that last-mile delivery accounts for half of the total CO₂ emissions and delivery costs of the overall journey of a single parcel. A popular mitigation approach involves installing parcel lockers, promising yet demanding new models for optimal last-mile distribution network configuration. This study introduces a novel stochastic Mixed Integer Optimization (MIO) model for the optimal placement of lockers across various demand scenarios, incorporating a customer behavior model based on utility functions and queuing characteristics for the selected location. We present an efficient optimization strategy inspired by Benders Decomposition and explore a scenario where last-mile operators utilize a government-established locker network. Our findings, based on real courier company data to model demand and utility functions from regional surveys to design the utility model of customer. Lastly, the study presents a Continuous Approximation (CA) model guiding optimal locker quantity and the impact of the final locations and service level. The study discusses method performance, practical application, and improvement opportunities, offering insights into sustainable urban logistics.

3 - Leveraging SROI for Enhanced Social Impact

Amirbahador Kouchakpourchali, Adriano Bisello

Leveraging Social Return on Investment (SROI) for Enhanced Social Impact offers a ground breaking approach to boosting the effectiveness of social initiatives through efficiency analysis, sustainable development, and decision support systems. This method quantifies the social, economic, and environmental value of projects, providing a monetary perspective on their impact. By integrating SROI into decision-making processes, organizations can pinpoint the most efficient and impactful ways to allocate resources, aligning closely with sustainable development objectives.

The paper highlights how incorporating SROI metrics into decision support systems aids in the systematic evaluation of social investments, facilitating a data-driven approach to choosing projects that yield the highest social returns. This not only enhances the strategic allocation of funds but also improves transparency and accountability, enabling organizations to communicate their achievements more effectively.

In essence, using SROI as a tool for enhanced social impact fosters a culture of evidence-based decision-making. It ensures that investments are directed towards initiatives with the greatest potential for positive social change, thereby contributing significantly to sustainable development efforts. This concise approach underscores the importance of SROI in optimizing social impact and advancing the global agenda for a more sustainable and equitable future.

Monday, 12:30-14:00 - Room: 44 (building: 116)

Multi-energy systems

Stream: OR in Energy

Invited session

Chair: Russell McKenna

1 - Exploiting synergies between heat supply and demand through endogenous modelling of building envelope retrofits

Julian Hermann, Corsin Taisch, Christoph Domenig, Russell McKenna

The built environment has a large share in energy consumption and CO₂ emissions in Europe, mainly caused by fossil fuel-based heat supply. In the energy transition context, a drastic decarbonisation of the existing building stock is required. Additionally, there is a significant potential for heat demand and emission reduction via envelope retrofits, which can also reduce required heat supply temperatures. Strong interactions occur between heat supply and demand, requiring a holistic assessment of investments on both sides. However, energy system optimisation models usually treat heat demand profiles as static inputs without considering envelope retrofits or treat retrofits in a simplified way using pre-defined sets. In both cases, the heat demand is exogenous and cannot be altered. Only a few studies endogenously consider envelope retrofits and their impact on heat demand.

This work presents a mixed-integer optimisation model to overcome the abovementioned limitations. Our model includes a simplified representation of the building's thermal behaviour, allowing us to consider investments in envelope retrofits and supply technologies endogenously. Comparing our methodology with existing approaches, we can show that considering envelope retrofits endogenously can yield more optimal results. Thus, our methodology enables exploiting synergies between investments in envelope retrofits and heat supply technologies.

2 - Integrating EV charging behaviour into a municipal energy system model to explore trade-offs between flexibility and battery degradation

Linda Brodnicke, Febin Kachirayil, Paolo Gabrielli, Giovanni Sansavini, Russell McKenna

Electric vehicles (EV) play a crucial role in achieving decarbonization targets and with increasing adoption, their charging patterns will have increasing impact on energy systems. In this presentation, we present a transferable methodology to assess the influence of EV charging strategies on the design and operation of district-level energy systems in urban, suburban, and rural municipalities in Northern Germany. We use the energy systems optimization model RE3ASON to assess the cost-optimal trajectory until 2050 subject to environmental constraints. We extend the detailed case studies by incorporating EV behaviour to evaluate the impact of passive charging, smart charging, and vehicle-to-grid (V2G) strategies on the energy system. In a two-stage optimization, the travel times and distances are sampled from a comprehensive German data set, aggregated in a way that ensures that energy and power limits of each EV are respected, and then implemented in the main optimization stage. Battery degradation is linearly approximated, which is particularly relevant for V2G modelling and a novel aspect of this study. Hence, our methodology can assess the trade-offs between the additional flexibility that V2G provides and the resulting costs in terms of battery degradation. Our findings provide quantitative estimates for the additional benefits that various charging methods may have in terms of reducing cost, facilitating photovoltaic integration and reducing battery storage requirements.

3 - A new modelling framework for offshore energy systems considering decarbonisation and decommissioning options for oil and gas infrastructure: a UK North Sea case study

Anna Peacock, Josef Koell, Pietro Bianchi Marzoli, Jianguyi Huang, Alfonso Martinez-Felipe, Russell McKenna

Exploiting synergies between the offshore wind and oil and gas (O&G) sectors can support decarbonisation goals, whilst exploiting disused hydrocarbon infrastructure for long-term economic value. Incorporating greater sectoral integration and diversity of energy carriers enables energy models to evaluate the impact of different policy levers more realistically. We therefore seek to quantify the economic and environmental benefits achievable by exploiting future synergies between the O&G and offshore wind sectors. This paper analyses scenarios with competing decarbonisation and repurposing alternatives and the resulting impacts on brownfield electrification and offshore hydrogen/ammonia production feasibility, as well as energy demands and emissions in the UK North Sea. Based on a mixed-integer linear programming (MILP) approach, the model determines optimal pathways for each of 242 O&G platforms while minimising total system costs up

to 2060. Operational constraints ensure technical viability of proposed technologies and through consideration of multiple energy carriers, a more realistic assessment of energy system integration is undertaken compared to previous studies. Offshore heat and power demands are calculated on a platform-specific level, and wind deployment scenarios are devised using a spatially-constrained bottom-up LCOE model. Future work should focus on integrating this tool within large-scale energy models, to improve the representation of the offshore system.

4 - Optimizing hybrid renewable energy systems through availability-based design

Luciana Yamada, Flávia Barbosa, Luis Guimarães

Hybrid renewable energy systems (HRES) have emerged as an alternative to single-source systems. With the advantage of combining different energy profiles and exploiting the complementarity of sources, HRES have demonstrated to be a good option for increasing the adoption of renewable energy (RE) technologies, ensuring a stable energy supply, and making the system more cost-effective by sharing operations and maintenance activities, electrical infrastructure, and space leasing. Efficiently designing HRES is essential to ensure stable energy production while maintaining cost-effectiveness. When designing an HRES, the goal is to identify the optimal combination of RE sources and determine their respective sizes and types of equipment. Furthermore, the design process must consider the availability of the system and the operational plan with the most effective maintenance strategies for each unique combination of energy sources. This study aims to analyse the cost competitiveness of an HRES, assessing the economic feasibility of: new HRES or transitioning existing installations into HRES with the addition of new RE sources (e.g. complement an existent wind farm with photovoltaic panels). A cost model is integrated into the optimization approach to estimate lifelong farm costs and maximize an economic indicator. The farm's availability is modelled using a Markov chain. In addition, this study seeks to identify cost-saving opportunities by integrating different energy sources.

Ethics and OR, societal complexity and public service

Stream: OR and Ethics

Invited session

Chair: [Dorien DeTombe](#)

Chair: [Cathal MacSwiney Brugha](#)

1 - An ethical complex societal problem, slums in developing countries.

Dorien DeTombe

Many cities in the world have areas which can be called slums. Slums are areas where poor people live in poor circumstances. The houses are not comfortable or convenient. Often leaking roofs, no good sanitation; toilets and douches are missing, no proper cooking devices or electricity. Slums create a lot of trouble, for the inhabitants themselves concerning safety and healthcare, but also for the whole city and for the country. Changing slums is a complex societal problem, which should be handled according to the directions of the Compram methodology. The Compram Methodology is a multidisciplinary approach for policy making on handling complex societal problems. These problems exceed the boundaries of a discipline. Therefore, a multidisciplinary approach is needed. In each complex societal problem there are elements of knowledge, power and emotion. All these elements should be addressed in the problem handling approach. The Compram methodology emphasizes the exchange of knowledge and understanding by communication among and between the experts, actors and politicians meanwhile keeping emotion in mind.

2 - The ethics of wanted and unwanted effects of government policies to handle the worldwide covid19 pandemic

Cor van Dijkum

Using systems theory and the tools of systems dynamics the worldwide spread of the covid19 pandemic can be analyzed as an effect of intrusions into ecosystems. The spreading of the covid19 virus started in 2019 in China as a local intrusion into an ecosystem. Subsequently the spreading of the virus in the world in 2019, 2020 and 2021 can be explained from this perspective. Thereby taking into account the globalizing of our world and the increasing influence of social media in the communication about and handling of the pandemics. The variables that explained the expanse of the pandemic are summarized in a global systems dynamic map. In this context the effect and efficacy of the governance policies to handle the pandemic is analyzed. Thereby taking into account economic inequality in and between countries and associated social unwanted effects on the present and next generation. Also the unexpected and disturbing outcomes of linear and nonlinear feedback loops on the way people reacted on government policies and the role social media played is studied. Thereby at last focusing on the ethical questions concerning wanted and unwanted effects of those policies. As a case study, with the aid of the system dynamics map a simulation model is developed to evaluate the policy of the government in the Netherlands and develop for this case alternative scenario's, with a better balance between wanted and unwanted effects on the population, thereby addressing ethical questions.

3 - Real and fake security, and the United Nations

Cathal MacSwiney Brugha

Real security protects and civilises, unites and reconciles, gives security. Fake security subjects and colonises, divides and rules, takes 'securities'. One example of fake security is where Israel seeks to secure its future by taking and subjecting two properties for itself, the Gaza Marine Gas Field, and the valuable trading route, from Asia to the Red Sea to the Mediterranean. In doing so, they are endangering the security of 2.4 million Palestinians in the Gaza Strip, 113 million Egyptians nearby, another 300 million people in the Middle East, and the security of future generations of Israelis. Another example is where, to secure for itself the valuable agricultural land of Ukraine, Russia is destroying the security of 37 million Ukrainian people, and the food security of millions in Africa, that are short of food. The United Nations Organisation could bring real security. A United Nations Protection Force (UNPROFOR) could join the United Nations Relief and Works Agency in the Near East (UNRWA), and bring security to the Gaza Strip, and then to Ukraine. Further, the 2 trillion (tn) dollars wasted on colonisers' military budgets could then be spent by UNPROFOR on further increasing global security, by reducing international crime: maritime 0.2 tn, cybercrime 6 tn, and organised crime 10 tn. Then to deal with global climate change. Only real climate security projects and actions provide any prospect of protecting future generations from global climate insecurity.

Monday, 12:30-14:00 - Room: 49 (building: 116)

Disaster Response: Search and Rescue, Resource Allocation and Impactful Prepositioning

Stream: OR in Humanitarian Operations (HOpe)

Invited session

Chair: Syed Tariq

1 - Planning effective emergency responses: K-adjustable robust optimisation for relief prepositioning

Fabricio Oliveira

Emergency response refers to the systematic response to an unexpected, disruptive occurrence such as a natural disaster. The response aims to mitigate the consequences of the occurrence by providing the affected region with the necessary supplies. A critical factor for a successful response is its timely execution, but the unpredictable nature of disasters often prevents quick reactionary measures. Preallocating the supplies before the disaster takes place allows for a faster response, but requires more overall resources because the time and place of the disaster are not yet known. This gives rise to a trade-off between how quickly a response plan is executed and how precisely it targets the affected areas. Aiming to capture the dynamics of this trade-off, we develop a K\$-adjustable robust model, which allows a maximum of K\$ second-stage decisions, i.e., response plans. This mitigates tractability issues and allows the decision-maker to seamlessly navigate the gap between the readiness of a proactive yet rigid response and the accuracy of a reactive yet highly adjustable one. The approaches we consider to solve the K\$-adaptable model are three-fold: Approximately, via a partition-and-bound method, and optimally via a branch-and-bound method as well as a static robust reformulation in combination with a column-and-constraint generation algorithm. In a computational study, we compare and contrast the different solution approaches and assess their potential.

2 - Relief Goods Prepositioning and Affectee Relocation Model For Compound Flooding

Syed Tariq, Muhammad Naiman Jalil, Muhammad Adeel Zaffar

Floods affect more people every year than any other natural disaster. Compound flooding is when multiple flooding events exacerbate the impact and duration of a flood. This paper studies relief logistics for compound flooding through the case of floods in Sindh province of Pakistan in 2010. The problem is treated as time-varying flows of relief goods from relief warehouses through periodic relief caravans to relief camps or storage close to them; and flows of affectees from shelter sites closest to them to more accessible shelter sites. This study concludes that relocation of affectees may be as cost effective as prepositioning of relief goods depending on optimal placement of relief warehouses. Factors that reduce logistics cost and improve demand fulfillment include prepositioning relief goods near shelters, frequent relief deliveries, and smaller storage modules that can reflect relief demand between caravan arrivals more closely.

3 - A novel approach for time-critical search planning in maritime search and rescue

Yingying Gao, Qingqing Yang, Guopeng Song, Roel Leus, Kewei Yang

In maritime search and rescue, an efficient search path is essential to maximize the success rate of the operation, typically indicated by the probability of containment and detection. This paper formulates a time-critical search problem, where a group of searchers moves through a discretized environment over time steps to locate the moving targets. Given the importance of finding drowning personnel timely, the decay factor of the survival rate is considered and incorporated into the objective function. To that end, we propose a novel approach specifically designed for this task, integrating Branch-and-Bound (B&B) with Reinforcement Learning (RL). To obtain more effective and non-myopic policies than handcrafted heuristics, we guide the branching process in path planning via RL and design a novel set representation and reward function for the bounding procedures associated with a policy, speeding up the convergence of unsupervised exploration. Our experimental results demonstrate the effectiveness of the proposed method, particularly on large realistic instances, improving upon the current state-of-the-art. The method can be generalized for different problem settings in operational decision support for maritime search and rescue.

4 - Approaches for Improving coordination in emergency care delivery in emerging economies context

Venkataramanaiah Saddikuti

Healthcare delivery in resource constrained environment is a big challenge for both healthcare professionals and policy makers. This is mainly due to higher levels of interdependencies among healthcare

providers. Of late, healthcare professionals are adopting the management science approaches for improving quality, efficiency and timely delivery of care at low cost. This mainly includes supply chain management approaches which is built based on theory of coordination and collaboration with suitable incentives. In developing countries where resources are scarce such coordination failures can have potentially severe impact on patient health. However, there is limited understanding about how coordination takes place across and within the different healthcare service providers and how this influence emergency care delivery. This presentation focuses on coordination and collaboration challenges in trauma care delivery in India using a patient survey. The findings suggest mechanisms to better integrate the processes in the care delivery which include setting-up referral processes, ambulance services, using third party coordinators and process improvement within the hospital following lean principles and suggestions for policy making are also highlighted.

Advancements in energy system optimization and analysis tools

Stream: Energy Management
Invited session

Chair: *Feng Qiu*
Chair: *Yuqun Dong*

1 - Unitcommitment.jl - An Open Source Julia Software Package to Accelerate Power System Research *Feng Qiu*

Unit commitment (UC) is one of the fundamental optimization problems in power system research, on which many essential grid applications are built, such as operations, planning, and markets. Many power system research projects involve the development of a UC model or its variant as a building block. Currently, most researchers prefer to write their own UC codes and use public data with their own tweaks. Although this approach allows authors more control over the code, the disadvantages are significant: it wastes time on reinventing the wheel, does not incorporate the state-of-the-art UC models/algorithms, and makes it difficult to benchmark with other work due to differences in implementation and datasets. In this work, we introduce an open-source Julia software package for UC-related research. The package not only implements state-of-the-art models/algorithms for UC problems but also provides great extensibility for secondary development and numerous test instances for benchmarking. This presentation will introduce the UC package and illustrate how it can be used to accelerate power system research.

2 - Benchmarking Building Energy Consumption Performance by A Nonparametric Least Squares Method *William Chung*

The Convex Nonparametric Least Squares (CNLS) method can be used to develop a benchmarking model represented by a set of hyperplanes. CNLS assumes that the regression function is either concave or convex. However, there may be instances where the regression function exhibits concave and convex patterns, rendering this assumption invalid. This paper addresses this drawback by proposing a new method called Concave-Convex Nonparametric Least Squares (C2NLS), which incorporates concavity and convexity constraints in CNLS. It is proved that C2NLS will have better goodness-of-fit performance than CNLS, but the number of hyperplanes will also increase. Since C2NLS contains both concave and convex portions, it is not sufficient to rely solely on the concavity assumption (or convexity assumption) during the benchmarking process. To tackle this issue, it is suggested that both concave and convex portions be used separately and combined with the resulting benchmarking scores. An illustrative example is provided,

and the energy performance of Hong Kong secondary schools is used to demonstrate the goodness-of-fit of C2NLS.

3 - Certification of MPC-based zonal controller security properties using accuracy-aware machine learning proxies *Manuel Ruiz*

Manuel Ruiz

The fast growth of renewable energies increases the power congestion risk. To address this issue, the French Transmission System Operator (RTE) has developed closedloop controllers to handle congestion. To ensure their proper functioning, RTE wishes to estimate the probability that the controllers ensure the equipment's safety. The naive approach to estimate this probability relies on simulating a large amount of randomly drawn scenarios, and use all the outcomes to build a confidence interval around the probability.

Although theory ensures convergence, the computational cost of power system simulations makes such a process intractable. The target of the present paper is to propose a faster process using machine-learning-based proxies. The amount of required simulations is greatly reduced thanks to an accuracy-aware proxy built with Multivariate Gaussian Processes. Using a proxy instead of the simulator however adds uncertainty to the outcomes. An adaptation of the Central Limit Theorem is thus proposed to include the uncertainty of the outcomes predicted with the proxy into the confidence interval. As a case study, we designed a simple simulator that is tested on a small IEEE network. Results show that the proxy learns to accurately approximate the simulator's answer, allowing a significant time gain for the machine-learning based process.

4 - Transformation of heterogeneous energy and planning storage capacity at regional strategic level: A financial derivative perspective *Yuqun Dong*

Yuqun Dong

Energy storage plays a key role in harvesting energy among heterogeneous energy sources. To transforming heterogeneous energy and planning storage capacity at regional strategic level, this paper simulates storage capacity settings for heterogeneous energy in a certain region (Jiangsu Province in China) from the perspective of investment portfolio. This paper then achieves the adjustments between generation side and storage side during operation under hedging ideology. At last, this paper takes thermal energy on storage side as an example to apply switching real option method in decision making for shifting from thermal energy into renewable energy during disposal. The conclusion shows that under a financial derivative perspective, planning of heterogeneous energy storage capacity is more efficient than existing regional plans and decision making of transformation contains investment triggers with higher option values. Thus, this paper can help the power system plan energy storage and manage heterogeneous energy more economically and completely at regional strategic level.

Sustainable food supply chains

Stream: Circular Economy, Remanufacturing and Recycling

Invited session

Chair: *Renzo Akkerman*

1 - Sustainable design of agricultural waste supply chain based on circular bioeconomy *Maryam Roudneshin, Amanda Sosa*

Maryam Roudneshin, Amanda Sosa

Among the United Nations' 17 Sustainable Development Goals, a critical aim is to provide "affordable, sustainable, and clean energy for all." Additionally, the rising urgency to ensure energy security and address global warming has highlighted the need to explore alternative energy

sources beyond fossil fuels. Leveraging agricultural waste for bioenergy production has emerged as a promising solution, offering an opportunity to mitigate environmental impacts while creating renewable energy. The success and attractiveness of this initiative to stakeholders and investors significantly depend on designing efficient supply chain networks, particularly in selecting optimal locations for biorefineries. This research sets out to design a supply chain network that prioritizes sustainability, encompassing economic, environmental, and social considerations. Initially, it employs a two-pronged approach, utilizing Geographic Information System (GIS) and MCDM, to pinpoint viable biorefinery locations, taking into account both environmental and economic constraints.

2 - Technologies Compatibility in a Capacitated Multi-Depot Routing distribution system for Food Sustainable Supply Chain

Seyed Mojtaba Sajadi, Fatemeh Khezerlouye Aghdam, Mahdi Bashiri

Food supply chains play a significant role in carbon emissions, and adopting emerging Industry 4.0 technologies can help mitigate this issue. The study investigates the compatibility of digital technologies at various echelons of the supply chain. Among the components of food supply chains, logistics are also particularly emissions-intensive and therefore require careful attention. This study presents a mixed integer linear programming mathematical model for selecting compatible technologies in food supply chains under a capacitated multi-depot vehicle routing distribution to minimise the supply chain's carbon footprint and to align with global carbon neutrality targets. To address the complexities of real-world scenarios, a metaheuristic algorithm is developed empowered by a Reinforcement Learning (RL) approach. The findings indicate that employing suitable technologies with optimal compatibility levels and implementing an optimum routing will lead to achieving a net-zero supply chain and reducing overall costs. The results underscore the importance of both technology selection and compatibility in attaining sustainability objectives.

3 - Network Design of an Insect-based Supply Chain

Sara Martins, Maria João Martins dos Santos

Insect farming has recently gained notoriety as a more sustainable alternative in the food and feed industry. Insects need less land, water, and feed than conventional livestock and can be fed on residual by-products from the food transformation industry that would otherwise be considered waste. By capitalizing on these factors, insect farming demonstrates a substantially smaller environmental footprint compared to conventional protein sources like cattle rearing and intensive agriculture. It is also important to design a sustainable supply chain, when defining the facility locations and suppliers selected. Thus, this work studies the network design problem of an insect-based supply chain, which needs to account for the by-products selected as feed and their distinct conversion rate into protein and processing costs.

4 - Scheduling organic waste collection operations in the circular economy

Marieke Brederveld, Renzo Akkerman, Sander De Leeuw

Currently, most organic waste in the Netherlands is used to produce biogas, but organic waste could also be used to produce higher value bio-based materials. This however adds additional considerations to the waste collection system, as it requires organic waste fractions to be collected separately, and to be processed within strict time limits (e.g., before mould can start to grow). These shelf life and separation requirements limit the possibilities to achieve economies of scale in collection. As a result, the environmental and cost benefits of waste valorisation are compromised.

This research contributes to the existing literature by considering the shelf life for low-volume waste collection. In order to increase the efficiency of the collection of concentrated organic waste, we develop a modelling approach to schedule the collection of multiple waste types, also considering the possibility of using different, possibly compartmentalised, vehicles. By allocating the vehicles, the aim is to keep waste separated while reducing the travelled distance. The results show trade-offs between for instance the value of biomass and the cost of

transport. In addition, the scheduling model provides insight in the usefulness of different vehicles types and sizes in waste collection activities in a more circular economy.

■ MC-24

Monday, 12:30-14:00 - Room: 83 (building: 116)

Clean Energy Supply Chains

Stream: Sustainable Supply Chains

Chair: Karsten Kieckhäfer

1 - Sustainable Supply Chain Design for CO₂ Electrolysis under CO₂-based Syngas Demand Uncertainty

Ozlem Mahmutogullari, Nevin Mutlu, Tarkan Tan, Floor Alkemade

The industrial sector is one of the major contributors to greenhouse gas emissions worldwide; it is therefore important to promote the use of alternative and emerging technologies that employ non-fossil-based feedstocks and renewable energy sources to meet the net-zero greenhouse gas emissions target. The electrolysis of CO₂ (CO₂E) is a carbon capture and utilization technology with the potential to produce chemicals and fuels by using water (H₂O) and electricity. We consider the generation of CO₂-based syngas (COH₂) by high-temperature CO₂ electrolysis as an alternative route to steam methane reforming that employs natural gas. Syngas is used in the chemical industry as a chemical building block and in the transportation sector as an intermediate for fuel production. Currently, fossil-based syngas is only consumed at its production sites. In this paper, we propose syngas as a merchant product, but since its market transition is new, there is a lack of comprehensive data on its demand. This uncertainty in syngas market demand can significantly affect the adoption and successful implementation of CO₂E technology. To deal with the uncertainty, we propose a robust supply chain design for CO₂-based syngas where strategic decisions regarding investments in the electrolyser locations and pipeline infrastructure and operational decisions regarding the amounts of syngas produced and CO₂ and syngas transported between echelons are made over a multi-period planning horizon.

2 - Exploring Transportation Alternatives in Carbon Capture and Storage Supply Chains

Lisa Herlicka, Frank Meisel

This presentation addresses the development of a supply chain customized for Carbon Capture and Storage (CCS) processes. Carbon Capture and Storage technology entails capturing CO₂ emissions at significant sources, transporting the captured greenhouse gas to designated storage sites, and permanently storing it within underground geological formations. While pipelines and maritime transport are being investigated in various studies due to their ability to transport large volumes of CO₂, vehicle transportation offers viable alternatives for the initial phase of CCS deployment or to address unavoidable emissions at a lower volume. We focus on the characteristics of emission sources, transportation modes and conditions, and permanent storage locations within the supply chain. Every element of the supply chain incurs annual investment and operational costs. The size of the network is determined by an annual emission capture target based on the existing CO₂ reduction targets. The problem is formulated as a mixed-integer linear program that aims to minimize the net present value over a specified planning horizon. The model is solved by CPLEX. Preliminary findings from a case study are presented, with analyses centered on costs associated with network participation, utilization of shared transportation infrastructure contingent upon mode selection and transport conditions, as well as storage expenses.

3 - Balancing Costs and Supply Security Risk in Renewable Energy Systems: A Bi-Objective Optimization Approach and an African-European Case Study

Veis Karbassi, Jörn Meyer, Grit Walther

The global net-zero transition requires new international energy links based on renewable energy carriers. Moreover, recent global energy supply disruptions emphasize the need to integrate risk into future energy systems. Against this background, we aim to construct affordable, secure energy supply chains for both importing and exporting countries by incorporating risk in energy system design. Our linear bi-objective quadratic optimization model analyzes total costs and security risk trade-offs in renewable energy production. Using the e-constraint in Python and Gurobi, we apply our model to a case of renewable energy production in Africa and its supply to Europe. Our findings reveal how characteristics of exporting countries, e.g., socio-political, environmental, and technological features and overall network structures, impact costs and security risk. Contrary to common assumptions of marginal risk improvements leading to significant additional costs, our model shows efficient risk mitigation is possible without a substantial cost increase. Our research further confirms that Africa's renewable potential can both satisfy its domestic energy demand and contribute to Europe's energy imports, underscoring the continent's role in global energy transitions. This work provides a comprehensive tool for decision-makers to evaluate cost efficiency vs. supply security trade-offs in renewable energy system design, enhancing resilience and reliability during global energy transition.

4 - Risk-sharing collaboration models for the production of Sustainable Aviation Fuels: an optimization model

Sophia Raaymann, Stefan Spinler

To decarbonize the aviation sector, the supply of sustainable aviation fuels (SAF) needs to be substantially increased. However, the production of SAF is associated with substantial risks, like demand risk, technological maturity risk, production cost risk or regulatory risk. To share these risks in SAF production, we propose risk-sharing collaborations between SAF suppliers and buyers. This approach fills a gap in existing research, which mostly focuses on technological aspects of SAF like its scalability or regulatory incentives. We create an optimization model that stochastically models SAF market prices and production costs, includes contract parameters like reservation fees or contract duration and models the heterogeneity in the SAF producer market through parameters like production efficiency, feedstock prices, penalties or geography. Firstly, a centralized scenario in which the whole supply chain's profit is maximized is evaluated. Secondly, a decentralized scenario using a Stackelberg game is evaluated. The model determines the collaboration model one risk-averse buyer and multiple suppliers would agree on to maximize their profits. The results indicate the best suitable risk-sharing collaboration model for both SAF buyers and suppliers.

1 - The one-commodity pickup and delivery location routing problem

Inmaculada Rodríguez Martín, Bencomo Domínguez-Martín, Hipólito Hernández-Pérez, Jorge Riera-Ledesma

The One-commodity Pickup and Delivery Location Routing Problem (1-PDLRP) is a new problem that combines characteristics of the Location and Routing Problem and the One-commodity Pickup and Delivery Traveling Salesman Problem. We are given a set of customers that provide or demand given amounts of a product, and a set of potential facility locations that can be opened or not in order to give service to the customers. Each facility has an opening cost and is the depot of a vehicle. The problem consists in deciding which facilities to open, assigning customers to open facilities, and designing the routes that connect each facility with its customers. The objective is to minimize the sum of the cost of the routes and the facilities. This NP-hard problem has not been previously studied. We propose for it two mathematical formulations, compare them, and present a branch-and-cut algorithm able to solve instances with up to 100 nodes.

2 - Solving the period travelling salesman problem

Sofia Henriques, Ana Paiais

Considering a time horizon with different periods, the Period Travelling Salesman Problem (PTSP) is defined on a directed graph with a depot and n customers, in which each customer has a required number of periods to be visited in. The objective of the PTSP is to assign each client to as many periods as it is required while determining the set of routes, one for each period, with minimum cost. Each route starts and ends at the depot and visits the clients assigned to that specific period only once.

The PTSP combines an assignment and a routing problem in a single problem, making it very difficult to solve to optimality, even for instances with few clients. Most of the works in the literature study heuristic methods for the PTSP, and the few exact methods in the literature only consider two periods in the time horizon, which is insufficient to model many real-life routing problems involving periodicity. We will present different flow-based compact formulations for the PTSP and we will use the concept of projection to derive new ILP formulations with fewer variables but exponentially-sized sets of constraints. Furthermore, we intend to propose new valid inequalities for the PTSP. The conclusions from our theoretical and computational study will be presented for instances with different characteristics.

3 - An exact algorithm for the multi-level multi-trip capacitated arc routing problem

Chenge Wei, Li Xue, Ada Che

This paper studies a real-life waste collection problem inspired by a waste collection system in China. In this system, manually operated vehicles (MV) collect small, dense forms of waste on streetsides and unload at waste collection huts. Meanwhile, vehicles with compressors (CV) collect larger waste demands from the huts and stores along the streets. The routing problems of MVs and CVs are regarded as an open multi-trip capacitated arc routing problem and a capacitated general routing problem, respectively. The multi-level problem aims to implement integrated optimisation of these two problems, which identify a set of routes for MVs and CVs with minimum travel costs that collect all waste. We first build a mixed integer linear programming (MILP) model to solve this problem. Moreover, we propose a set covering model and a logic-based benders decomposition framework that embeds a branch and price (B&P) algorithm. Based on the feature of the two-level problem, this framework decomposes the set covering model into the master problem of MV routes and the sub-problem of CV routes. To solve the sub-problem, the B&P algorithm is then applied. We adopt three classic CARP branching schemes and extend the label-setting algorithm to generate CV routes with negative reduced costs. Preliminary experiments show that, compared with solving the MILP model with commercial optimisation software, the proposed framework can effectively improve the gap within the same time limitation.

4 - Smart refueling decisions using reinforcement learning approach: a case study from trucking industry

Amin Asadi, Myrthe Kruit, Behzad Mosalla Nezhad, Sebastian Piest

Transportation services play a pivotal role in international trade, with trucking companies handling approximately 77% of inland freight. Refueling costs constitute a substantial portion of operational expenses, ranging between 20% and 30% in Europe. To address the complexities of refueling decisions in the trucking industry, we propose a data-driven sequential decision-making framework. Our approach captures price fluctuations along trucking routes, incorporating factors such as region, time, and possible price agreements with gas stations. Leveraging the Markov Decision Problem and Reinforcement Learning (RL) methods, we develop a robust framework capable of minimizing refueling costs while accounting for fuel price uncertainties. In a real-world case study conducted with a logistics company in the Netherlands, our framework demonstrated significant savings in refueling costs. Through extensive experimentation, we validate the superiority of our approach compared to in-practice and benchmark policies, showcasing the practical utility and effectiveness of our proposed framework.

1 - Learning Directed Acyclic Graphs using Integer Linear Programming

James Cussens

Directed acyclic graphs (DAGs) can be used to represent conditional independence relations in joint probability distributions, and, with suitable assumptions, can additionally represent causal relations between the variables in a distribution. The problem of learning the 'best' DAG from data is often cast as a discrete optimisation problem - which is known to be NP-hard. Encoding this problem as an integer linear program (ILP) is not hard, but solving large instances requires a careful combination of cutting (adding linear constraints during solving) and pricing (adding new ILP variables during solving). In this talk I will discuss 'lessons learned' in tackling the DAG-learning problem with ILP and discuss the more ambitious task of learning models (causal and non-causal) which allow for latent variables.

2 - Simultaneous Training and Optimization of Few-Bit Neural Networks through a Multi-Objective MILP

Simone Milanesi, Ambrogio Maria Bernardelli, Stefano Gualandi, Hoong Chuin Lau, Neil Yorke-Smith

Training neural networks using combinatorial optimization solvers has gained attention, especially in low-data scenarios. Utilizing advanced solvers like mixed integer linear programming can precisely train networks without relying on intensive GPU-based methods. We focus on few-bit discrete-valued neural networks, including Binarized Neural Networks (BNNs) and Integer Neural Networks (INNs). These lightweight architectures are notable for their ability to operate on low-power devices, for example, by being implemented using boolean operations. Our proposed method involves training a network for each class pair of the classification problem and using a majority voting scheme for the output prediction. The optimization process adheres to the principles of robustness and sparsity by employing a multi-objective function. We compare this approach, named BeMi, to existing solver-based and gradient-based methods, particularly in few-shot learning contexts with BNNs. We also assess the trade-offs between INNs and BNNs. Empirical results on the MNIST dataset show that BeMi achieves higher accuracy (up to 81.8%) with a significant reduction in active weights, outperforming previous methods.

3 - Optimal Shapelets Tree for Time Series Interpretable Classification

Stefano Gualandi, Lorenzo Bonasera

Time series shapelets are a state-of-the-art data mining technique for supervised classification tasks in time series domains. Shapelets are time series subsequences that retain the most discriminating power in time series. The main advantage of shapelet-based methods is their great interpretability. We propose a novel Mixed-Integer Programming model to optimize shapelets discovery based on optimal binary decision trees. Computational results for a large class of datasets show that our approach achieves performance comparable with state-of-the-art shapelets-based classification methods. To the best of our knowledge, this is the first approach based on optimal decision tree induction for time series classification.

1 - Reducing Cognitive Load in Declarative Business Process Models

Hugo A. López

Explainability in Artificial Intelligence (AI) is pivotal for enabling humans to comprehend both the outputs produced by algorithms and the underlying reasoning processes. Extending it to the realm of Business Process Management (BPM), it encompasses understanding the models generated by process discovery algorithms and deciphering the recommendations offered by process engines during process enactment.

Declarative Business Process Modelling (DBPM) emerges as a crucial framework within BPM, focusing on elucidating cause-effect relations between activities. This type of explanation is particularly valuable in knowledge-intensive processes with humans in the loop.

In this talk, I summarize our recent endeavors aimed at alleviating the cognitive load associated with understanding declarative business process models. Our approach draws insights from process modeling, event-based systems, human-computer interaction, and game design.

Specifically, we will explore techniques such as enhancing traceability, ensuring semantic transparency, leveraging explain-by-example methodologies, and employing design-via-metaphors. These strategies are designed to refine the visual representations of declarative process notations, thus enhancing the accessibility and comprehensibility of knowledge-intensive processes for novice users.

2 - Leveraging Manifold Learning for Constrained Counterfactual Explanations in Process Outcome Prediction

Jari Peeperkorn, Alexander Stevens

Harnessing the potential of machine and deep learning architectures within Predictive Process Analytics (PPA) has yielded promising results, particularly in predicting future process outcomes. However, the opacity inherent in these algorithms poses a significant challenge for human decision-makers, limiting their understanding of the rationale behind the predictive outputs. In response, counterfactual explanations, serving as human-understandable 'what if' scenarios, offer intuitive insights into the decision-making process behind undesirable predictions. Nevertheless, generating counterfactual explanations encounters specific challenges when dealing with the sequential nature of business process cases in PPA. To address this, our paper introduces REVISED+, a novel data-driven approach aimed at generating more

feasible and plausible counterfactual explanations tailored to the complexities of sequential process data. The counterfactual generation algorithm is guided through high-density regions of the process data distribution, and Declare language templates are used to capture sequential patterns among the process activities. This enables REVISED+ to improve the feasibility and plausibility of the generated counterfactual explanations. Finally, we assess the validity of our counterfactuals with metrics that define the key properties of a good counterfactual.

3 - Exploring Explainable Predictive Process Monitoring *Andrei Buliga*

This project focuses on advancing the field of Explainable Predictive Process Monitoring (XPPM) by developing novel techniques for generating explanations in PPM, and developing novel evaluation metrics. Furthermore, we aim to understand the interplay between different types of explanations and how they can be leveraged to improve the explainability process.

The first aspect of this research concerns the generation of counterfactual explanations in PPM, which are explanations that suggest what should be different in the input instance to change the outcome of a PPM model. Firstly, an evaluation protocol measuring the quality of the generated counterfactual examples and the evaluated method's performance is proposed. In the second part, a methodology is proposed, that involves the use of genetic algorithms, incorporating temporal background knowledge at runtime. The methodology aims to generate counterfactual explanations that guarantee the satisfaction of the background knowledge, a critical aspect of counterfactual generation in XPPM. A second aspect of this research is developing novel explainability method by using previously proposed Business Process Management (BPM) techniques to adapt explanation generation mechanisms. A third aspect of this research project endeavours to combine various explanation techniques to streamline the search process and improve the overall quality of explanations, by leveraging multiple explanation types proposed in the literature.

4 - Dynamic Condition Response Graphs as Explainable AI in Business Processes *Thomas Troels Hildebrandt*

We present the uses of Dynamic Condition Response (DCR) Graphs as Explainable AI in Business Process Management. DCR Graphs is a declarative process modelling notation that can be used by domain experts to model, simulate and support workflows and business processes in a flexible and maintainable way. The first version of the DCR notation was published in 2010 in a PhD project of Mukkamala at IT University of Copenhagen, as part of the Trustworthy pervasive healthcare services project lead by Hildebrandt. The notation was further extended and accompanied by the first graphical editor as part of an industrial PhD project by Slaats (2015), at the danish company Exformatics and IT University of Copenhagen. The development was significantly advanced during the EcoKnow.org research project (2017-2021) lead by Hildebrandt, leading to major additions to the language, such as sub processes, decision modelling and data, and the development of tools for transformation of natural language textual regulations and requirements to formal models process models, lead by López (2018), award winning algorithms for process mining (lead by Back and Slaats), and the creation of the company DCR Solutions (DCR-Solutions.net), offering industrial strength design, simulation and execution tools. Recently, the tool chain has been extended in the PhD project of Cosma (2024) with tools for mining hierarchical and timed DCR Graphs and for transforming DCR Graphs to Petri Nets.

Advancements of OR-analytics in statistics, machine learning and data science 3

Stream: Advancements of OR-analytics in statistics, ma-

chine learning and data science

Invited session

Chair: *Laura Albert*

Chair: *Gerhard-Wilhelm Weber*

1 - Variable-size mixed-variable black-box optimization for central air conditioning configuration *Shun Tanaka, Shiho Watanabe, Hiroshi Morita*

We consider the variable-size mixed-variable black-box optimization, which involves variable dimensions and optimizing a diverse and numerous sets of variable types through a black-box function. In this study, we extend the mixed-variable black-box optimization problem and use estimation methods to achieve more efficient optimal solution search. This approach can be applied to find the equipment configuration of a central air conditioning system that provides an optimal configuration that minimizes overall installation and operating costs.

2 - Detecting Drug Transfers via the Drop-off Method: A Supervised Model Approach using AIS Data *Britt van Leeuwen, Maike Nutzel*

This paper introduces a novel approach for detecting sea-based drug transfers through the utilization of Automatic Identification System (AIS) data. We propose a model for the detection of the 'drop-off' method, a prevalent technique for contraband smuggling at sea. Unlike the prevailing focus on unsupervised methods in existing maritime anomaly detection research, our paper introduces a supervised model tailored to the 'drop-off' method, particularly in the context of fishing vessels. We have developed a machine learning algorithm, employing a Long Short-Term Memory (LSTM) model capable of identifying 'drop-offs'. This model holds the potential for integration into real-time surveillance systems. Furthermore, our model demonstrates generalizability, thereby enhancing maritime security efforts and providing invaluable assistance in countering drug traffic on a global scale.

3 - Designing small-scale coordination clusters for academic office space usage *Paul Bouman, Wilco van den Heuvel*

At universities, academic staff performs many different tasks, resulting in heterogeneous demand for focused work, meetings, teaching, general collaboration and discussion with colleagues. These heterogeneous demands raise the question how appealing and effective working conditions can be guaranteed when shared workplaces are a necessity, i.e. when there are fewer desks than FTE's available for a department. While large homogeneous office gardens with flex-work places maximize sharing, in practice they are disliked. We introduce the alternative idea of assigning clusters, groups of 7 to 9 employees, to a fixed number of desks and offices. Within a cluster coordination then occurs at a smaller scale, providing employees more agency in how to organize their office space usage. An optimization model is developed that assigns employees to clusters based on a short survey, previous office pairings and supervisory relations. In the model, we aim to have a fair distribution of "crowding" over the clusters for different times of the week. We develop several alternative objectives and ways to measure crowding and fairness in the model. The model was used during a pilot project with an academic department and some experiences from this project are discussed. We observe that for different clusters different coordination behaviour emerged. Also, junior employees more often found the opportunity to work in a private office compared to the situation with a fixed allocation.

4 - Computable general equilibrium study of migration in Europe: the cases of Germany and Slovakia *Veronika Mitkova*

The aim of our study is to investigate the effects of migration on wages and incomes, and the impact of more liberal migration policies, which increase labour quotas by 5 per cent. The study focuses on the impact of migration in 21 regions, with particular attention to Slovakia and Germany. The study was based on data from the Global Trade Analysis Project database, using experimental designs by Walmsley, Ahmed and Parsons, and adjusted to capture current global migration flows. According to the findings of the study, the arrival of new, unqualified

workers has a negative impact on the actual wages of unqualified residents, with the real wages falling by nearly 3 per cent, and the real wages of skilled workers rising by 0.73 per cent. Similarly, due to the arrival of new qualified immigrants, the real wages of qualified residents have declined by 2.62 per cent, while the real wages of non-qualified immigrants have increased by 0.53 per cent. These results can help policy makers to develop policies aimed at maximizing the benefits of migration. Finally, the study provides a new insight into the wage effects of migration in different areas, particularly in Germany and Slovakia.

Vehicle routing I

Stream: Combinatorial Optimization

Invited session

Chair: Irene Loiseau

Chair: Rajan Batta

1 - Solution of a practical Vehicle Routing Problem for monitoring Water Distribution Networks

Dario Vezzali, Reza Atefi, Manuel Iori, Majid Salari

In this work, we introduce a generalization of the Vehicle Routing Problem for a specific application in the monitoring of a Water Distribution Network (WDN). In this problem, multiple technicians must visit a sequence of nodes in the WDN and perform a series of tests to check the quality of water. Some special nodes (i.e., wells) require technicians to first collect a key from a key center. The key must then be returned to the same key center after the test has been performed, thus introducing precedence constraints and multiple visits in the routes. To solve the problem, a Mixed Integer Linear Programming model and an Iterated Local Search have been implemented. The efficiency of the proposed methods is demonstrated by means of extensive computational tests on randomly created and real-world instances.

2 - UAV Search and Routing Planning in a Disaster Area

Rajan Batta, Nastaran Oladzad, Esther Jose, Miguel Lejeune

The goal of this work is to identify the best Search and Routing Planning (SRP) for an Unmanned Aerial Vehicle (UAV) to maximize the total number of casualties detected in a disaster-affected area within a limited mission duration. First, a Mixed-Integer Non-linear Programming (MINLP) model is formulated. To linearize the model, continuous search time variables are discretized such that each can only take a finite number of possible values. Therefore, the resulting Mixed Integer Linear Programming (MILP) problem is an approximation of the original problem. This approximation is shown to be highly accurate; however, it can not solve problems with more than 10 search regions in less than three hours. Second, an exact solution approach is introduced, which is capable of solving problems of size 14 or smaller during the given computational time limit. Next, an efficient clustering heuristic is suggested to solve larger instances of the original problem with more than 200 search regions. Finally, a case study based on the 2023 Turkey-Syria earthquakes is presented. The results reveal, despite thousands of casualties remaining missing for weeks in the real-life scenario, the proposed solution methods can help detect 60-77% of casualties within a few hours in provinces under study.

3 - A bilevel two-echelon multi-commodity routing problem to facilitate greener last-mile logistics

Ade Fajemisin, David Rey

An increasing number of cities are incentivising the consolidation of deliveries to micro-hubs outside Low-Emission Zones (LEZs), and the use of lower footprint delivery vehicles such as cargo bikes and electric delivery vehicles inside the LEZs. We therefore present a single leader,

multiple follower bilevel two-echelon multi-commodity routing problem to facilitate greener last-mile logistics. The leader represents a platform, whose goal is to minimize both emissions and the number of delivery vehicles operating in an LEZ. The leader is also responsible for allocating parcels to micro-hubs, as well as allocating parcels to last-mile Delivery Service Providers (DSPs). On the other hand, the followers seek to minimize routing costs and maximize client satisfaction. There are two types of followers: first-mile followers who deliver parcels to micro-hubs, and last-mile followers who pick up the parcels from the micro-hubs and deliver to their final destinations. Each first-mile follower solves a Vehicle Routing Problem (VRP) with time windows, while each last-mile follower solves a pickup and delivery, time-dependent VRP with time windows. We also develop a cutting plane algorithm to solve our bilevel problem and evaluate the effect of our approach on several problem instances using real-world data.

4 - The adoption of self-driving robots in last mile health-care logistics

Somayeh Allahyari, Gu Pang, Yufeng Zhang, Keru Duan

The adoption of self-driving robots across various delivery applications presents a transformative shift in urban logistics, offering enhanced efficiency, agility for fast and on-time deliveries, sustainability through zero emissions, and reduced human contact. The onset of the COVID-19 pandemic expedited the execution of robot delivery roll-out strategies, leading to market size growth and attracting new competitors. This study investigates the integration of autonomous delivery/collection robots into last-mile logistics for synchronised collection of medical samples in the healthcare sector, where vans are equipped with self-driving robots. A multi-echelon network topology is adopted by leveraging insights from the UK public health service's (known as NHS) hub and spoke network strategy which prioritises faster and more reliable screening test results, including for cancer. The study addresses the new operational challenges associated with implementing this new self-driving robot technology, focusing on routing and scheduling logistics problems. To tackle these challenges, a mixed-integer linear programming model and an Adaptive Large Neighbourhood Search (ALNS) metaheuristic algorithm are developed. Experimental results demonstrate the effectiveness of both the model and the algorithm in optimising last-mile service in the healthcare sector, shedding light on the potential of self-driving robots to revolutionise healthcare logistics.

Continuous Solvers

Stream: Software for Optimization

Invited session

Chair: Maxime Dufour

1 - Progress towards a new interior point solver for HiGHS

Julian Hall

HiGHS is open-source software for large scale linear optimization, and has established itself as offering the best benchmark performance due to its innovative interior point (IPM) solver for LP, and powerful MIP solver. In particular, the IPM solver has been hailed as a game-changer for the field of open-source energy system modelling. However, for some instances, the IPM solver is still prohibitively expensive. A new IPM solver is now under development, and this talk will outline the progress that has been made, as well as setting out other recent developments in HiGHS.

2 - Decomposition, Cutting Planes and Column Generation with Interior Point Methods

Jacek Gondzio

In this talk we shall explain the reasons why interior point methods (IPMs) deliver particularly attractive features when they are applied in the context of decomposition methods, cutting plane schemes and column generation techniques. These features include: (1) generating epsilon-subgradients in Benders and Dantzig-Wolfe decomposition, (2) finding (stable) well-centred solutions of restricted master problems, (3) delivering on-demand accuracy in column generation. It goes without saying that these features cannot be delivered by the simplex-based solvers. Some of the advantages will be illustrated when solving very large discrete optimal transport problems.

3 - Latest developments for mixed-integer nonlinear programming in Artelys Knitro

Maxime Dufour, Florian Fontan, Hugo Chareyre

1 Introduction

Artelys Knitro is a mathematical programming solver for nonlinear and mixed-integer nonlinear problems. As input, it accepts linear structures, quadratic structures and black-box functions, with if possible, their first and second-order derivatives. Knitro relies on derivative-based algorithms to find locally optimal solutions. Knitro finds the global optimum for convex problems. For non-convex problems, Knitro converges to a first order stationary point (e.g. local optimum) for continuous models and is a heuristic for mixed-integer problems.

2 Recent improvements for MINLP applications

In this talk, we will present the algorithms implemented in Artelys Knitro for mixed-integer nonlinear problems in Knitro 14.0, and detail the recent developments for the nonlinear branch-and-bound algorithms. Since Artelys Knitro 13.0, the nonlinear branch-and-bound has been fully rewritten as parallel and deterministic. The algorithm has been greatly improved by adapting the ideas developed for mixed-integer linear programming. Those features include specific presolve operations and cuts for nonlinear applications, a heuristic portfolio to provide effort effective search improved better branching strategies and a restart procedure. It opens several perspectives for future developments and extensions for nonlinear models that we will present during this talk. We will show the improvements on the classical datasets for mixed-integer nonlinear problems.

two steps. First, individual dose-response curves are estimated on observational data. Since historically treatments are not assigned at random but the allocation of doses depends on pre-treatment covariates, observational data may be subject to selection bias. To address this bias, we employ causal machine learning methods. Second, we formulate the individual dosage allocation as an optimization problem to maximize the expected causal profit while adhering to constraints, such as budget limitations or fairness criteria.

2 - Exploring Learning to Rank for Optimal Treatment Allocation

Toon Vanderschueren, Wouter Verbeke, Felipe Moraes, Hugo Proença

Efficiently allocating treatments while accounting for operational constraints constitutes an important challenge across various domains. In marketing, e.g., using promotions to target potential customers and boost conversions is limited by the available budget. While much research focuses on estimating causal effects, there is limited work on learning how to optimally allocate treatments. Existing methods for uplift modeling or causal inference that estimate treatment effects do not consider how the estimated effects relate to decisions made based on these estimates. Therefore, a potential downside of these methods is that the resulting predictive model may not be aligned with the operational context, resulting in prediction errors being propagated to the optimization problem and, subsequently, a suboptimal allocation policy. We explore an alternative approach based on learning to rank. In this approach, the idea is to directly learn an allocation policy that prioritizing instances for treatment in terms of their treatment effect. We explore different ranking metalearners and propose an efficient sampling procedure for the optimization of the ranking model to scale our methodology to large-scale data sets. We validate our methodology empirically and show its effectiveness in practice through a series of experiments on both synthetic and real-world data.

3 - Optimizing Treatment Allocation in the Presence of Interference: a Causal Machine Learning Approach to the Influence Maximization Problem

Daan Caljon, Jente Van Belle, Wouter Verbeke

In Influence Maximization (IM), the objective is to select the optimal set of entities in a network to target with a treatment so as to maximize the total effect. For instance, in marketing, the objective is to target the optimal set of customers that maximizes the total response rate, resulting from both direct treatment effects on targeted customers and indirect, spillover effects that follow from targeting these customers.

In selecting the optimal set of entities, current IM methods typically overlook the features of the entities. Nevertheless, these features might contain important information on the propagation of effects through the network. Moreover, current methods assume that all entities that receive treatment will be activated (e.g., buy the product), ignoring varying susceptibilities to treatment depending on an entity's characteristics.

Current IM approaches mainly rely on assumptions about how effects propagate through the network, potentially leading to a suboptimal selection of entities. To improve upon current methods, we propose a causal machine learning approach which estimates both direct and spillover effects from data, instead of relying on assumptions. After training a causal estimator on observational data, in a second step, treatment allocation is optimized by integrating the treatment effect estimates into current IM algorithms. This two-step approach is shown to improve the expected influence spread compared to traditional methods.

4 - Estimating continuous treatment effects from observational data: An empirical evaluation of methods, scenarios, and challenges

Christopher Bockel-Rickermann, Tim Verdonck, Wouter Verbeke

Our study investigates the use of causal machine learning for estimating the effects of continuous treatments from observational data. This is a challenging task, as in such data treatments are often not randomly assigned, leading to "confounding", a systematic difference between

Chair: *Wouter Verbeke*

1 - A predict-then-optimize approach for uplift modeling with continuous individual treatment effects

Simon De Vos, Wouter Verbeke

Uplift modeling facilitates decision optimization by predicting the instance-dependent impact of treatments on specific outcomes. In a setting with binary treatments, cost-sensitive causal classification enables the classification of instances into treated or untreated groups, aiming to maximize the expected causal profit which is the core objective. We extend upon the binary treatment case and allow for continuous individual treatment effects, represented by a dose-response curve. From an application perspective, the motivation for integrating continuous treatments stems from the potential convexity of individual dose-response curves. Deciding which entities to assign what dosage is a function of individual dose-response curves, which reflect the change in positive outcome probability per assigned dosage, and the cost and benefit parameters of treatment and positive outcomes of the specific problem setting at hand. Our predict-then-optimize approach involves

units that were assigned different treatments. Additionally, many modern decision-making problems are high-dimensional and complex, hindering the application of traditional statistical causal inference techniques, and calling for specialized data-driven methodologies. We review established causal machine learning methods for continuous treatment effect estimation, as well as previously presented benchmarking datasets. The goal of our study is to derive sensitivities of model performance to different data-generating processes and accompanying challenges, such as the strength of confounding, the amount of training data, and the complexity of relationships between variables of interest. To further aid practitioners and researchers, we also test several state-of-the-art methodologies from supervised learning in the capability to estimate treatment effects, aiming to further aid the decision when to adopt targeted methodologies for continuous treatment effect estimation.

1 - Minimizing Quasi-Self-Concordant Functions by Gradient Regularization of Newton Method

[Nikita Doikov](#)

We study convex optimization problems with a Quasi-Self-Concordant smooth components. Our problem class naturally interpolates between classic Self-Concordant functions and functions with Lipschitz continuous Hessian. Previously, the best complexity bounds for this problem class were associated with trust-region schemes and implementations of a ball-minimization oracle. In this talk, we show that for minimizing Quasi-Self-Concordant functions we can use instead the basic Newton Method with Gradient Regularization. For unconstrained minimization, it only involves a simple matrix inversion operation (solving a linear system) at each step. We prove a fast global linear rate for this algorithm, matching the complexity bound of the trust-region scheme, while our method remains especially simple to implement. Then, we introduce the Dual Newton Method, and based on it, develop the corresponding Accelerated Newton Scheme for this problem class, which further improves the complexity factor of the basic method. As a direct consequence of our results, we establish fast global linear rates of simple variants of the Newton Method applied to several practical problems, including Logistic Regression, Soft Maximum, and Matrix Scaling, without requiring additional assumptions on strong or uniform convexity for the target objective.

2 - Universal Gradient Methods for Stochastic Convex Optimization

[Anton Rodomanov](#)

We develop universal gradient methods for Stochastic Convex Optimization (SCO). Our algorithms automatically adapt not only to the oracle's noise but also to the Hölder smoothness of the objective function without a priori knowledge of the particular setting. The key ingredient is a novel strategy for adjusting step-size coefficients in the Stochastic Gradient Method (SGD). Unlike AdaGrad, which accumulates gradient norms, our Universal Gradient Method accumulates appropriate combinations of gradient- and iterate differences. The resulting algorithm has state-of-the-art worst-case convergence rate guarantees for the entire Hölder class including, in particular, both nonsmooth functions and those with Lipschitz continuous gradient. We also present the Universal Fast Gradient Method for SCO enjoying optimal efficiency estimates.

3 - High-Order Reduced-Gradient Methods for Composite Variational Inequalities

[Yurii Nesterov](#)

In this talk, we present a unified approach for constructing efficient methods for solving Variational Inequalities, presented in a composite form (CVI). This class of problems is close to the maximal one, which can be efficiently treated by numerical methods. At the same time, it is more difficult than the class of Convex Optimization Problems. All efficient methods for VI use an additional "extra-gradient" step. We propose a new interpretation of this step as a cutting plane for the optimal solution, reflecting the interaction of the monotone operator with the boundary of the feasible set. Contrary to the existing approaches, we introduce a universal extragradient step, which does not depend on the particular class of CVI. Consequently, our framework can be used for developing optimal methods for CVI, which are based on high-order oracles.

1 - Equilibrium Carbon Permit Supply and CCS Investment under Uncertainty

[Nicola Comincioli](#), [Peter Kort](#), [Jacco Thijssen](#), [Sergio Vergalli](#)

This paper examines the optimal behavior of carbon-intensive companies operating under the European Union Emission Trading System (EU ETS), wherein they are obligated to purchase emission permits on the secondary market if their emissions exceed their allowance. Specifically, we consider the scenario where these companies, typically required to procure permits at market prices, are endowed with the (real) option to invest in Carbon Capture and Storage (CCS) technology to mitigate their emissions and, thus, permit expenditures. The central challenge is the determination of the optimal time for investment in CCS within a stochastic framework characterized by uncertainty in EU ETS permit prices. To enhance realism, we address the problem for a heterogeneous group of companies distinguished by their respective costs of implementing CCS systems, reflecting varying degrees of environmental consciousness across industrial sectors. Furthermore, we incorporate an increasing floor for permit prices to mirror policy efforts aimed at promoting green transition by elevating emission costs. We solve this problem analytically and through numerical simulations calibrated with real market data. In addition to offering insights into individual company behaviors, the findings can inform decision-makers in refining environmental policies, particularly regarding the management of permits price floor and its potential to expedite the green transition.

2 - Dynamic Stability of Cooperative Investment under Uncertainty

[Martijn Ketelaars](#)

This article models the inherent cooperative and non-cooperative incentives of stakeholders in investment projects in a novel way by combining concepts from cooperative game theory and real options theory. As stakeholders have outside options, in the sense that they may terminate negotiations with the current coalition and join another, we introduce and analyze a coalitional and dynamic stability concept. We show that investment projects, in which cooperation between stakeholders is necessary, are more prone to coalitional instability when there are insufficient synergies between the stakeholders. We characterize the proportional investment scheme as the investment scheme that maximizes the total project value and that results in the earliest investment timing. A failure to implement proportional investing leads to the formation of a smaller, less efficient, coalition. The vulnerability to fail is

exacerbated in a market that is characterized by high profit growth and low profit uncertainty, or vice versa. Finally, we explicitly consider one-leader investment projects and characterize the prioritized investment scheme that maximizes the value of the leader. We show that the same market conditions govern the stability of the prioritized investment scheme, which contributes to the robustness of our results.

3 - Investment decisions in Energy Storage Systems: a real options approach

Marta Castellini, Chiara D'Alpaos, Fulvio Fontini, Michele Moretto

Renewable energy generation plays a crucial role in the energy transition. Nevertheless, as many Renewable Energy Sources (RES) are intermittent, specifically photovoltaic (PV) generation, there are often mismatches between energy production and consumption. These mismatches can be partially reduced by storage systems. In this paper we investigate the investment decision in a PV power plant coupled with a Battery Energy Storage System (BESS), namely an Energy Storage System (ESS). In our setting, the BESS is connected to the national grid and the PV plant: energy can be produced, purchased from the grid, stored, self-consumed, and fed into the national grid. PV production and energy consumption loads evolve stochastically over time. In addition, BESS are costly, and energy stored has an opportunity cost, which depends on the prices of energy purchased from the national grid and energy fed into the grid, respectively. Nonetheless, BESS can significantly contribute to increase ESS managerial flexibility and, in turn, ESS value. In detail, we investigate the optimal BESS capacity that maximizes ESS expected net present value. We also analyze ESS management costs to provide insights on ESS optimal management strategy.

4 - Green Technology Investment: Announced vs. Unannounced Subsidy Retraction

Xingang Wen, Verena Hagspiel, Peter Kort

Policy uncertainty affects firms' investment decisions and the corresponding societal welfare (total surplus). One common perception is that, policy uncertainty has negative welfare effects, and therefore, the regulator should make policy changes "transparent" by announcing future policy changes. This paper investigates a firm's green technology investment decision in a dynamic setting, where it decides about the investment timing and size under the market uncertainty in the form of stochastic investment costs, and under the policy uncertainty in the form of unannounced subsidy retractions. In particular, we consider two scenarios, depending on whether the regulator announces the subsidy retraction in advance. We show that, a larger policy uncertainty makes the firm invest earlier and less. Besides, the subsidy retraction announcement can motivate the firm to invest early to "take" the subsidy, which is a typical rent-seeking behavior. This has two negative welfare implications: an inefficiently small investment size due to the early investment, and a large subsidy cost due to the firm "taking" the subsidy. Comparing the total surplus generated by firm's investment decision in the two scenarios, we conclude that the rent-seeking behavior in the announced scenario makes it possible that not-announcing the retraction threshold yields a larger total surplus. This result is robust for several common subsidy types.

1 - Real data EIT reconstruction using virtual X-rays and deep learning

Siiri Rautio

In electrical impedance tomography (EIT), the aim is to recover the unknown conductivity of a target by injecting currents and measuring boundary voltages through electrodes. It is a nonlinear and severely ill-posed inverse problem. We introduce a new reconstruction algorithm for EIT, which provides a connection between EIT and traditional X-ray tomography, based on the idea of "virtual X-rays". We divide the exponentially ill-posed and nonlinear inverse problem of EIT into separate steps. We start by mathematically calculating so-called virtual X-ray projection data from the measurement data. Then we perform explicit algebraic operations and one-dimensional integration, ending up with a blurry and nonlinearly transformed Radon sinogram. We use neural networks to remove the higher-order scattering terms and perform deconvolution. Finally, we can compute a reconstruction of the conductivity using the inverse Radon transform. We demonstrate the method with experimental data. This is a joint work with Melody Alsaker, Fernando Moura, Juan Pablo Agnelli, Rashmi Murthy, Matti Lassas, Jennifer Mueller, and Samuli Siltanen.

2 - Space-Variant Total Variation boosted by learning techniques for subsampled imaging problems

Davide Evangelista

In solving inverse problems with subsampled forward operators, a crucial aspect is choosing an efficient regularizer. The isotropic Total Variation (TV) functional is often used uniformly, to get gradient-sparse solutions, but it tends to remove small details and smooth edges. To address this, we propose a space-variant weighted isotropic TV regularization, whose weights can be determined by a neural network. This talk includes a rigorous theoretical analysis and presents experiments confirming the potential of the proposed approach to enhance the quality of undersampled CT reconstructions.

3 - On stochastic first order optimization methods for deep learning applications

Federica Porta, Giorgia Franchini, Valeria Ruggiero, Ilaria Trombini, Luca Zanni

First order stochastic optimization methods are effective tools for the minimization of problems arising in deep learning applications. In this work we study a stochastic first order algorithm which rules the increase of the mini-batch size in a predefined fashion and automatically adjusts the learning rate by means of a monotone or non-monotone line search procedure. The mini-batch size is incremented at a suitable a priori rate throughout the iterative process in order that the variance of the stochastic gradients is progressively reduced. The a priori rate is not subject to restrictive assumptions, allowing for the possibility of a slow increase in the mini-batch size. On the other hand, the learning rate can non-monotonically vary along the iterations, as long as it is appropriately bounded. Convergence results for the proposed method are provided for both convex and non convex objective function. The low per-iteration cost, the limited memory requirements and the robustness against the hyperparameters setting make the suggested approach well-suited for implementation within the deep learning framework, also for GPGPU-equipped architectures. Numerical results on training deep neural networks for multi-class image classification show a promising behaviour of the proposed scheme with respect to similar state of the art competitors.

4 - Accelerating convergent Plug-and-Play methods

Andrea Sebastiani, Tatiana Bubba, Luca Ratti

Plug-and-Play methods are obtained replacing with off-the-shelf denoisers, the proximal operator in many first order proximal optimization algorithms. Under suitable hypothesis, it is possible to derive the functional whose proximal operator corresponds to a particular class of denoisers, referred to as Gradient Step denoisers. This characterization result allows for the interpretation of Plug-and-Play schemes as the minimization of an underlying non-convex cost function, enabling the study of the convergence of such methods. In particular, this analysis can be further extended to ensure the convergence of several accelerated methods. The non-convexity of the cost function strongly limits

any improvement in the theoretical convergence rate. However, the numerical experiments empirically demonstrate the benefits of this acceleration, that allows to reduce the computational demand and workload required to compute the reconstruction of an image.

1 - A Vehicle Routing Problem with Divisible Deliveries and Pickups under Uncertainty

Francesca Vocaturo, Alessandro Gobbi, Daniele Manerba

Most e-commerce companies design combined delivery-pickup logistics systems, where the collection of unsatisfactory items is ensured along with the traditional distribution of products to customers. In this context, a successful option is to solve a Vehicle Routing Problem with Divisible Deliveries and Pickups (VRPDDP) where each customer requiring both a pickup and a delivery service may be served, if beneficial, in two separate visits. In the version of the problem analyzed in our study, there are mandatory delivery and pickup demands that must be fulfilled by a fleet of homogeneous vehicles. In addition, it is needed to ensure that a percentage of optional pickups is served. Optional pickup demands are affected by uncertainty and random variables are used for their representation. In this sense, we refer to our problem as stochastic VRPDDP and model it as a two-stage stochastic program with recourse. More specifically, a set of routes is designed at the first stage. At the second stage, when uncertainty is revealed, it may be impossible to implement the solution as planned at the first stage. Then, two different recourse actions are carried out. The computational experiments confirm the usefulness of using stochastic programming in realistic setting.

2 - Variational Auto-Encoders and Generative Adversarial Networks for scenario generation

Enza Messina, Michele Carbonera, Michele Ciavotta

In this talk, we address the problem of learning multivariate distribution from empirical data aimed at scenario generation. Capturing the complex spatio-temporal relationship among multiple variables is a challenging task. Copula based models are usually applied in this context for their ability to separate the multivariate structure from its marginal distributions. However, when considering real case studies choosing the right family of copula models may be difficult. To overcome these difficulties, in this work, we propose a data-driven (or model-free) approach by adopting generative methods. In particular, we explore the use of Variational Auto-encoders and Generative adversarial Networks, for learning the multi-variate joint probability distribution of link speeds on a road network, using real sensor data. Experimental results, conducted on three distinct benchmark datasets, highlight the potential of the proposed model in generating new scenario samples of multivariate variables that preserve correlations among variables, while producing samples that faithfully represent the empirical marginal distributions.

3 - On the Attended Home Delivery Problem with Recovery Options: Econometrical analysis and solution approaches

Daniele Manerba, Valentina Bonomi, Renata Mansini, Roberto Zanotti

We study an Attended Home Delivery Problem with Recovery Options (AHDP-RO) as a supporting tool for companies that want to ensure timely services within the complex attended home delivery setting. Since missed deliveries can negatively impact customer satisfaction and delivery costs, the problem considers customers' availability through different profiles identifying the probability of them being at home for each time slot of the delivery day. When a missed delivery occurs, the problem implements different recovery policies based on the customer's preferences (e.g., leaving the package in a safe spot, scheduling a second delivery attempt on the same day, or directing the package to a designated collection point). To optimize the scheduling of deliveries and minimize routing costs, we present a Mixed-Integer Linear Programming formulation in which the cost of a missed delivery is proportional to a penalty (determined by the chosen recovery option) and to the probability of not finding the customer at home during the selected time slot. Moreover, different solution approaches (based on various exact or heuristic technologies) are proposed to solve real-size instances and, in turn, support a multi-attribute analysis for obtaining useful economic and managerial insights on the decisional process we are facing.

4 - Sampling methods for multi-stage robust optimization problems

Francesca Maggioni, Fabrizio Dabbene, Georg Pflug

In this talk, we consider multi-stage robust optimization problems of the minimax type. We assume that the total uncertainty set is the cartesian product of stagewise compact uncertainty sets and approximate the given problem by a sampled subproblem. Instead of looking for the worst case among the infinite and typically uncountable set of uncertain parameters, we consider only the worst case among a randomly selected subset of parameters. By adopting such a strategy, two main questions arise: (1) Can we quantify the error committed by the random approximation, especially as a function of the sample size? (2) If the sample size tends to infinity, does the optimal value converge to the "true" optimal value? Both questions will be answered. An explicit bound on the probability of violation is given and chain of lower bounds on the original multi-stage robust optimization problem provided. Numerical results dealing with a multi-stage inventory management problem show that the proposed approach works well for problems with two or three time periods while for larger ones the number of required samples is prohibitively large for computational tractability. Despite this, we believe that our results can be useful for problems with such small number of time periods, and it sheds some light on the challenge for problems with more time periods.

1 - Operations Research Games under Uncertainty and Distributional Ambiguity

Xuan Vinh Doan, Tri-Dung Nguyen

We introduce a new solution concept of (robust) least chance decisions for cooperative games under uncertainty and distributional ambiguity, which is motivated by the concept of least core solutions for deterministic cooperative games. We develop a framework to find those decisions and compute their (robust) least chance dissatisfaction for cooperative games under normally distributed uncertainty and moment-based distributional ambiguity. We demonstrate how the proposed framework can be applied to operations research games such as linear production games with detailed analytical results.

2 - Sequencing situations with position-dependent effects under cooperation

Alejandro Saavedra-Nieves, Manuel Alfredo Mosquera-Rodríguez, María Gloria Fiestras-Janeiro

This paper innovatively addresses the effect of cooperation on sequencing situations with position-dependent effects. Specifically, we ensure convexity of the associated sequencing games under the fulfilment of certain conditions on the neighbour switching gains. Besides, we propose two families of allocation rules based on sharing the neighbour switching gains under two procedures, each one giving a path from the initial order to an optimal order. From a theoretical point of view, an axiomatization of both families of allocations is provided, and their stability is also ensured under those conditions related with convexity. Finally, we analyse the specific sequencing problems arising from the total flow time minimization under the consideration of exponential positional effects.

3 - Water banks as bargaining games

María Borrego-Marín, Amparo Mármol, Victoriana Rubiales Caballero, Miguel A. Hinojosa

Water banks constitute a market mechanism that enables the voluntary reallocation of flows to respond to both temporary and structural changes in the availability of this resource. Good management of water banks makes it possible to reduce social conflicts associated with water scarcity through temporary or permanent reallocation of the resource based on the supply and demand of users. Negotiation games are a methodology to formalise and analyse the consequences of the interaction between potential water sellers and buyers. The possibility of cooperation between the agents involved is analysed to obtain consensual solutions that improve the result that they can individually ensure. In particular, Nash and Kalai-Smorodinsky bargaining solutions are proposed to identify feasible reallocations of water that satisfy certain principles of rationality. In the absence of negative externalities, the water transfers that are determined with these solutions allow improving the economic efficiency associated with the use of water.

4 - A Coopetition Index for Coalitions in Simple Monotone Games.

Michele Aleandri, Marco Dall'Aglio

The measurement of power for players in cooperative games traditionally focuses on the effort that single players exert on every coalition of other players. A more recent stream of works focuses on the evaluation of the power of groups (see Flores R., Molina E., Tejada J. (2019), Evaluating groups with the generalized Shapley value 4OR, 17 (2), 141-172) together with an estimation of their interactions, defined in Grabisch M., Roubens M. (1999), An axiomatic approach to the concept of interaction among players in cooperative games. International Journal of Game Theory 28: 547-565, as the average of finite order differences for the players in the coalition.

We examine the use of such indexes in the context of monotone simple games and we verify that the original interaction index captures the group's relationship in terms of collaboration and competition for two players, but fails to do so for larger groups.

We therefore define a collaboration-competition index that is based on the notion of essential criticality and coincides with Grabisch and Roubens's interaction index for two players. We analyze its properties and we put the index at work with some applications.

Applications of polynomial optimization

Stream: Conic Optimization: Theory, Algorithms, and Applications

Invited session

Chair: David de Laat

1 - Optimality and uniqueness of the D₄ root system

Nando Leijenhorst, David de Laat, Willem de Muinck Keizer

The spherical code problem asks how to arrange N points on the unit sphere in dimension n such that the distance between the closest pair of points is maximized. We prove that for 24 points in dimension 4, the D_4 root system is the optimal configuration. We prove this by showing that it is the unique solution for the kissing number problem in dimension 4, up to isometry. For this we use a semidefinite programming relaxation of the second step of the Lasserre hierarchy for spherical codes, for which we obtain an exact optimal solution by rounding the numerical solution using the techniques of [Cohn, de Laat, Leijenhorst, 2024+].

2 - Convergence analysis of the sum-of-squares hierarchy for polynomial optimization

Lucas Slot

The moment-SOS hierarchy provides a sequence of lower bounds on the minimum of a polynomial f on a semialgebraic set S . These bounds can be computed by solving semidefinite programs of increasing size, corresponding to sum-of-squares representations of increasing degree. As a consequence of powerful Positivstellensätze from real algebraic geometry, the bounds are known to converge to the true minimum of f under mild assumptions on the feasible region S . In this talk, we discuss some recent progress on the asymptotic behaviour of the SOS-hierarchy for certain special choices of S , such as the unit hypercube.

3 - Spectral bounds for set avoiding graphs via polynomial optimization

Tobias Metzloff

The chromatic number of a set avoiding graph has a lower spectral bound, which is often sharp. We assume that the vertices and the avoided set are invariant under a crystallographic reflection group. Then the spectral bound can be expressed as the minimum of a polynomial on a basic semi-algebraic set. We compute several bounds for interesting graphs analytically and numerically.

Based on joint work with Evelyne Hubert, Philippe Moustrou and Cor-dian Riener.

Invited session

Chair: Ioannis Dimitriou

Chair: Tuan Phung-Duc

1 - Fair and efficient sharing: dynamic pricing control in batch service system with strategic customers

Ayane Nakamura, Tuan Phung-Duc

Transportation systems, such as bus systems, are important areas in which to apply models for strategic customer behavior. We then propose a dynamic pricing mechanism, in which the fees for each customer and the timing for the service commencement depend on their experienced time cost, for batch service (shuttle bus) systems, to achieve operational efficiency and passenger fairness under a strategic joining/balking scheme. In this dynamic pricing scheme, the monopolist decides the fee for each customer such that all customers on the same shuttle have rigorously equivalent utilities (including waiting costs), and, if the total time cost for waiting customers exceeds certain criteria, the monopolist lets the shuttle depart even though the number

of customers is less than the full capacity. For this model, we show an equilibrium strategy within certain parameters, and propose an algorithmic procedure that rigorously calculates the transition probability between states under long-term observation and construct a Markov chain for the number of waiting customers. Based on the results, we present a method for calculating performance measures such as the mean of social welfare, monopolist revenue, and experienced utility. Throughout some numerical experiments, we show that the dynamic pricing control has the potential to improve both fairness among customers and performance efficiency.

2 - Data-Driven Population Tracking in Large Service Systems

Fernando Bernstein

We develop a stylized theoretical framework for the problem of tracking the population in a service system with noisy input and output observations. The motivation for the project is the problem of tracking the population of passengers in the TSA area at an airport in real time using noisy data from people counters. Our goal is to devise and analyze policies that use past people counter data to estimate the population in the system over a finite and discrete time horizon. We evaluate the performance of policies in two distinct settings. In the busyness tracking problem, the objective is to track whether the policy correctly detects if the system census is larger or smaller than a threshold. In the population tracking problem, the objective is to minimize the expected magnitude of the estimation error in each period. We show that our problem is more challenging than dynamic learning problems studied in the bandit literature. In the busyness tracking problem, we derive a general lower bound on the cumulative expected loss that grows linearly with the time horizon. In the population tracking problem, we prove another general lower bound on cumulative expected loss that is on the order of the square of the time horizon. Given this complexity, we develop and analyze policies that achieve the best possible performance in terms of the growth rate of cumulative expected loss. Furthermore, we investigate the benefit of conducting periodic inspections of the true census in the system.

3 - Effects of spectrum handoff delay on secondary users in cognitive radio networks

Yuta Kamioka, Ken'ichi Kawanishi, Tuan Phung-Duc

The rapid development of ICT (Information and Communication Technology) in recent years has led to the problem of wireless bandwidth depletion. One of the technologies to alleviate the problem is to make use of CRNs (Cognitive Radio Networks). This is a technology for efficient and dynamic use of frequencies. In CRNs, users are divided into PUs (Primary Users) and SUs (Secondary Users). PUs are licensed users to occupy the bandwidth. On the other hand, SUs are not licensed users and can use the bandwidth only if SUs know that PUs are not present by sensing because PUs have preemptive priority over SUs. Therefore, spectrum handoff in CRNs critically affects performance of SUs.

This paper considers CRNs and analyzes performance measures of SUs. In particular, we take into account of spectrum handoff delay in CRNs and compare performance of SUs with and without the handoff delay. We construct system models by continuous-time Markov chain having transition rate matrix with block tridiagonal structure, which is called QBD (quasi-birth-death) process, to efficiently compute the stationary distribution. We show numerical examples of the performance of SUs in terms of delay in system. We discuss the effects of spectrum handoff delay on the performance measures for the model with the spectrum handoff delay and the conventional model without the handoff delay.

4 - Externalities in the M/G/1 queue: LCFS-PR versus FCFS

Nikki Levering, Royi Jacobovic, Onno Boxma

Externalities are the costs that a user of a common resource imposes on others. In a stable M/G/1 system, the externalities created by an arriving customer with known service requirement equal the total waiting time that others will save if she would reduce her service requirement to zero. Naturally, these externalities are stochastic, and the corresponding analysis relies heavily on the underlying service discipline.

In this talk, we compare the externalities under the last-come first-served with preemption (LCFS-PR) and first-come first-served (FCFS) service distributions. Specifically, we establish a joint decomposition for the externalities under LCFS-PR and FCFS in terms of a bivariate compound Poisson process. This decomposition can be used to derive several other results regarding the externalities: moments, asymptotic approximations as the service requirement goes to infinity, asymptotics of the tail distribution, and a functional central limit theorem. This is joint work with Royi Jacobovic (Tel-Aviv University) and Onno Boxma (TU/e).

Stochastic and Deterministic Global Optimization

*Stream: Stochastic and Deterministic Global Optimization
Invited session*

Chair: Thi My Le Le

1 - Advanced numerical methods for Lipschitz global optimization

Dmitri Kvasov, Yaroslav Sergeyev

Decision-making problems defined as global optimization problems of an objective function subject to a set of constraints arise in various application fields. The objective function and constraints can be black box and difficult to evaluate functions with unknown analytical representations. This means that there are black boxes associated with the functions which, given the values of the input parameters, return the values of the corresponding functions and the optimizer knows nothing about how these values are obtained. Therefore, one of the main goals in this context is to develop fast global optimization algorithms that produce reasonably good solutions with a limited number of function evaluations. We will discuss various deterministic approaches based on the Lipschitz continuity assumption to construct efficient and reliable numerical methods to solve the mentioned problems. Among these, the divide-the-best scheme for developing and studying numerical methods in a unitary way, the index scheme for managing non-convex constraints and the local tuning on the function's behaviour will be examined in particular (see https://doi.org/10.1007/978-3-030-54621-2_764-1). Some recently proposed high-precision techniques (including the infinite computing paradigm <https://www.theinfinitycomputer.com>) will also be considered.

This work was partially supported by the Italian INdAM GNCS Project 2023, number CUP_E53C22001930001.

2 - Inverse Optimization for Imputing Constraint Parameters in Mathematical Programs

Archis Ghate

In a typical (forward) optimization problem, a decision-maker uses given values of model parameters to compute the values of decision variables. The goal in inverse optimization (IO) is instead to infer parameters that render given values of decision variables optimal. Most papers on IO utilize duality to impute objective function parameters. A corresponding literature for imputing constraint parameters is essentially non-existent, even for linear programs. The difficulty is that these IO problems include nonconvex bilinear constraints and/or objectives. We will discuss models and solution algorithms designed to tackle these difficult problems. We will illustrate key ideas through the motivating problem of imputing transition probabilities in Markov decision processes (MDPs). If time permits, we will also extend these ideas to inverse semi-definite programs (SDPs) and inverse Quadratic Programs (QPs), where matrices on the left-hand-sides of constraints are unknown.

3 - Global optimization in operations research problems

Anatolii Kosolap

Most optimization models of operations research problems are multimodal. Such problems are NP-hard. They include the optimization problems with continuous and Boolean variables. Existing methods and solvers do not allow us to effectively find optimal solutions to such problems. We propose to use the original method of exact quadratic regularization to solve such problems. Quadratic regularization allows us to transform the multimodal problems into the problem of the maximum of the norm of a vector on a convex set. For solving the transformed problem, it is enough to have a local solver. We solved many multimodal problems using this method. In particular, linear and quadratic knapsack problems, packing problems, scheduling problems, reliability of systems, and many others. We have performed significant comparative computational experiments. Our method allowed us to obtain significantly better solutions for various operations research problems.

4 - Solving Stochastic DC programs with DC constraints

Thi My Le Le, Hoai An Le Thi, Van Ngai Huynh

We consider a class of stochastic difference-of-convex-functions (DC) programs, which are optimization problems where the objective function is the expected value of a stochastic DC function based on a probability distribution, while the constraint functions are DC. There have been many methods developed for convex (nonconvex) stochastic optimization problems without constraints or with convex constraints; however, methods designed for nonconvex and nonsmooth constrained programs are rare. The DC algorithm (DCA) is acknowledged in the literature on deterministic optimization as one of the few efficient algorithms for solving large-scale nonconvex and nonsmooth optimization problems. Using penalty techniques, we transform nonconvex constrained stochastic DC programs into standard stochastic DC programs and introduce novel stochastic DCAs to solve the resulting stochastic DC programs. The convergence analysis of the proposed algorithms is thoroughly investigated, and numerical experiments are performed to evaluate their behaviors.

Chair: Stefan Creemers

1 - Discrete Optimization: A Quantum Revolution?

Stefan Creemers, Luis Fernando Pérez

We use Grover's algorithm to build quantum algorithms that can be used to solve discrete optimization problems on a universal quantum computer. We use our quantum algorithms to solve the binary knapsack problem, and highlight a number of challenges that are faced when effectively using Grover's algorithm to solve discrete optimization problems. We also present a number of procedures that can match the performance of the best classical procedures for solving the binary knapsack problem and demonstrate that quantum computing may cause a revolution in the field of discrete optimization.

2 - Discrete optimization: Limitations of existing quantum algorithms

Luis Perez, Stefan Creemers

We investigate the limitations of existing quantum algorithms to solve discrete optimization problems. First, we discuss the quantum counting algorithm of Brassard et al. (1998), and show that it has performance that is equivalent to that of a brute-force approach when approximating the number of valid solutions. In addition, we show that a

straightforward application of Grover's algorithm (referred to as GUM by Creemers and Pérez in an earlier paper) dominates any quantum counting algorithm when verifying whether a valid solution exists. Next, we discuss the nested quantum search algorithm of Cerf et al. (2000), and show that it is dominated by a classical nested search that uses an approach such as GUM to find (partial) solutions to (nested) problems. Last but not least, we also discuss amplitude amplification (a procedure that generalizes Grover's algorithm), and show (once more) that it may not be possible to outperform GUM.

3 - Analog Quantum Computing for Combinatorial Optimization Problems

M. Yassine Naghmouchi, Wesley Coelho

In this proposed talk, we delve into the promising realm of quantum computing, specifically focusing on the utilization of neutral atom-based Quantum Processing Units (QPUs) and analog quantum computing methodologies to tackle combinatorial problems. We will discuss how neutral atom-based QPUs, with their precise control and manipulation capabilities, provide a robust platform for quantum computation. Practical examples and case studies will be presented to demonstrate the efficacy and potential of these quantum computing approaches. Additionally, we will discuss the current state of research, challenges, and future prospects in this rapidly evolving field.

1 - Investigating the Impact of Anchoring Effects and Market Manipulation on Wealth Distribution in Agent-Based Asset Markets

Bin-Tzong Chie

In recent years, the proliferation of automated trading strategies has underscored the significance of anchoring effects in financial markets. Despite efforts to tailor these strategies to user preferences, anchoring effects persist, influencing decision-making among traders. This phenomenon, observed by Tversky and Kahneman, affects buyers and sellers differently, leading to market distortions. Additionally, the presence of market manipulators further complicates market dynamics, exacerbating wealth distribution imbalances. To better understand these dynamics, we employ agent-based modeling, allowing for the exploration of interactions among different agents in the market. Through simulations, the study aims to shed light on the impact of anchoring effects and market manipulation on wealth distribution, offering valuable insights for financial regulators. This study aims to address these challenges by constructing an agent-based asset market incorporating anchored traders and market manipulators. Inspired by previous research, the study aims to understand how different scenarios and manipulative practices influence market efficiency and wealth distribution using agent-based modeling.

2 - A Promising Approach to the El Farol Bar Problem: Hysteresis in Decision Making

Burak Çetiner, Hakan Yasarcan

The El Farol Bar Problem (EFBP) is introduced by W.B.Arthur(1994) to present Complexity Economics. Arthur claims that if all agents use deductive reasoning, either all attend the bar or all stay home. Thus, deductive reasoning fails. Therefore, all agents use inductive reasoning with different strategies in forming their expectations about weekly attendance, which then be used in this binary decision-making process. Arthur states that when inductive reasoning is used, the mean attendance always converges to the bar capacity. The best-known strategy in

the literature in terms of minimizing the variance in the attendance values is random attendance with the unstated assumption that the bar capacity is known. We suggest a new agent type called Yasarcan-Çetiner agents, which use a hysteresis structure in decision-making. These agents persist on keeping their current decisions as it is for a number of trials before switching their decisions; each individual agent has specific persistence thresholds. Yasarcan-Çetiner agents perform better than all existing agent types in the EFBP literature in terms of improving bar utilization and in minimizing the variance of weekly attendance values. It is not necessary for Yasarcan-Çetiner agents to know the bar capacity a priori; learning the bar capacity is an emergent collective behavior of the swarm, which is another contribution. We anticipate that Yasarcan-Çetiner agents will be used in other type of economic decision-making problems.

3 - Enhancing Household-Level operational decision making with Machine Learning

Aoubakr Achraf El Ghazi, Ulrich Frey, Evelyn Sperber

Agent-based modeling (ABM) presents an effective framework for analyzing complex and highly interconnected systems such as the electricity market. With the ongoing energy transformation, understanding the individual decisions of actors such as households with PV-storage systems (PVS), heat pumps (HP), and electric vehicles (EV) is crucial. However, ABMs for the electricity market on a national level with complex interconnected actors face scalability limitations with regard to their individual decision making. Though, aggregating actors into representative entities and applying a single decision strategy fails to consider the diversity of individual decision-making processes. Moreover, this oversimplified approach neglects the influence of the varying attributes of the individual actors. To solve this problem, we propose leveraging machine learning (ML) techniques to address these requirements while controlling the scalability challenge. The main idea is to utilize ML methods to learn and predict the aggregation of individual actor decisions. Central to our approach is a uniform forecasting of aggregated demand time series for all actor types, i.e., PVS, HP, and EV. The underlying demand time series result from applying optimization models specific to each actor type. The results show similarly good predictions for PVS, HP, and EV. This method enables a more nuanced understanding the individual impact of decision-making processes of households on a national level.

4 - Liability in Blockchain Consensus: An Analysis of the Incentives Set by Proof of Stake Voting Mechanisms

Sascha Hägele

In the landscape of blockchain consensus mechanisms, Proof of Stake (PoS) has emerged as a prominent alternative to traditional Proof of Work protocols, as evidenced by the consensus change of the second largest cryptocurrency, Ethereum. In PoS systems, validators are tasked with securing the network and validating transactions based on the amount of cryptocurrency they 'stake' as collateral. However, ensuring the integrity of PoS networks requires mechanisms to incentivise validators to behave honestly and to penalise malicious actors. Drawing on insights from economic theory, in particular principal-agent theory, this paper examines the role of liability in the PoS consensus, focusing in particular on the incentives created by voting mechanisms designed to enforce compliance. By developing a mathematical model and using an agent-based simulation approach, I analyse the impact of these mechanisms on validator behaviour and network security. My research highlights the importance of aligning incentives to deter undesirable actions while promoting network resilience and decentralisation. By comprehensively examining liability within blockchain consensus, this paper contributes to a deeper understanding of the dynamics at play in PoS systems. By elucidating the interplay between stakeholder incentives and protocol design, my findings provide valuable insights for the development and governance of blockchain networks in the pursuit of robust and secure decentralised ecosystems.

MCDM for project portfolio problems

Stream: Multiple Criteria Decision Analysis
Invited session

Chair: *Maria Barbati*

1 - Modeling Criteria and Project Interactions in Portfolio Decision Analysis with the Choquet Integral

Matteo Brunelli, Salvatore Corrente

We introduce a comprehensive framework for addressing multicriteria portfolio decision analysis challenges, particularly in situations where between-projects independence or within-project independence may not be assumed. The Choquet integral preference model, a widely adopted non-additive integral in multicriteria decision analysis, is employed to consider potential interactions between projects and between criteria. In this context, to streamline the preference model and maintain problem manageability, we opt for the 2-additive Choquet integral, which assigns values only to individual entities and pairs of entities. An illustrative example demonstrates the application of our approach to a multicriteria portfolio decision analysis problem.

2 - Robust De Novo Programming Under Different Uncertainty Sets and its Application to Renewable Energy Sector

Noureddine Kouaissah

This paper proposes robust type models of de novo programming (R-DNP) using cardinality-constrained robustness via interval-based and norm-based uncertainty sets. The R-DNP has not been researched, and we aim to fill this literature gap. In particular, we develop the robust counterpart of the weighted DNP (W-DNP), Chebyshev DNP (C-DNP), and extended DNP (E-DNP) models to consider different uncertainty sets and incorporate the decision makers' preferences. Methodologically, the proposed approach extends the conventional DNP model to enable it to solve uncertain coefficients for each decision variable on the left-hand side of each objective function and on the total budget, overcoming a limitation of the current multi-criteria solution procedure of the DNP approach. The proposed methods provide decision makers more flexibility to express their level of conservatism and preferences by setting aspiration levels. The proposed method's usefulness over the standard DNP is demonstrated by providing an illustrative example. Moreover, we validate the proposed formulations for solving real-world problems through a hypothetical application: optimizing the renewable portfolio for electricity generation in Morocco. The results confirm the proposed methodologies and show that they can assist decision makers in determining the optimal system design for sustainable electricity generation under uncertain conditions.

3 - The Deck-of-Cards-Based Ordinal Regression

Maria Barbati, Salvatore Greco, Isabella Lami

We define a new multicriteria decision-aiding procedure to manage decision-makers' preferences. The preferences are elicited by conjugating the deck of cards method with the ordinal regression approach. The deck-of-cards method allows the DM to express the ranking order of reference alternatives and the intensity of preferences between reference alternatives. An ordinal regression procedure is then used to define a multicriteria value function that represents the ranking of the reference alternatives as well as the preference intensity. We show how this methodology can be usefully applied to different forms of a value function, such as weighted sum, Choquet integral, and additive value function.

Methods and Algorithms of Decision Support

Stream: Decision Support Systems

Invited session

Chair: Pavlos Delias

1 - Scalable algorithms for throughput time constrained decision-intensive processes

Simon Voorberg

This work is on using Reinforcement Learning for Optimal Information Acquisition in Decision Processes. We use a model-based Deep Reinforcement Learning (DRL) technique to optimize large scale decision-intensive processes. We extend a basic model for decision-intensive processes with lead time constraints and parallel information acquisition. In many situations multiple sources of information can be requested in parallel, such that we can put a maximum throughput time constraint on the process while still minimizing for the total effort that is invested in the process. These extensions cause the state space of the problem to explode and we aim at showing the value of DRL for problems like this. For small size problems we make a comparison to the optimal solution and for larger size problems we introduce some heuristics against which we compare the performance of the DRL solution. For the small size problems our solution performs within a small range from the optimal solution. For the larger case we show significant improvements compared to the heuristics.

2 - On a heuristic algorithm for optimal coordination of fire-fighting helicopters on large wildfires

Marta Rodríguez Barreiro, María José Ginzo Villamayor, Fernando Pérez Porras, Sílvia Lorenzo-Freire, María Luisa Carpena Rodríguez

This work presents a complete model for the optimal planning of helicopter operations during the extinguishing of a large wildfire. In large wildfires, many resources work together and must be coordinated in order to extinguish the wildfire in the shortest possible time while minimizing the damage caused. It is the responsibility of the fire coordinator to plan the work of these resources. To assist in this task, a model has been developed to find the optimal planning of helicopters in a fire-fighting situation. The model determines which aircraft should work on the fire and at what time. It also selects where the helicopters should load water and where they should rest. Using the level of efficiency associated with each area of the wildfire at each time, provided by the coordinator, the model also indicates at which points on the wildfire each helicopter will drop water. It also considers the fact that the aircraft work in groups, forming elliptical circuits that share water load and drop areas. It also takes into account Spanish aviation regulation. The model is presented in a time-extended graph, which allows the evolution of the wildfire to be reflected. The complexity of the model makes it impossible to solve it in a short time with the tested commercial solvers. Therefore, a heuristic based on the Simulated Annealing technique was implemented. The heuristic was tested with realistic data instances, achieving good results in a short time.

3 - An Adaptive Large Neighborhood Search Algorithm for Order Batching Problem

Ahmet Çınar, Betül Ahat, Mehmet Emre Altun, Bahar Umman, Meltem Sanisoğlu

Over the past decade, amidst the rise of e-commerce enterprises and the transformative impact of the Covid-19 pandemic, the Order Batching Problem (OBP) has garnered significant attention. This heightened focus is fueled by the substantial volume of order transactions and the subsequent exponential expansion of warehouse dimensions, comprising multiple zones. These complexities have underscored the potential for over-costing in picking operations, prompting the adoption of intelligent solutions. Despite this, scant attention has been devoted to

addressing OBP at the scale of Trendyol Group, a prominent player in Turkey and an increasingly influential international e-commerce entity offering a diverse array of product categories. This study particularly focuses on an OBP problem that groups orders into worklists for warehouse pickers, with the objective of maximizing the average number of items per zone. This approach seeks to minimize the duration of item picking for pickers, as a higher concentration of items per zone enables greater efficiency in item collection. To address this problem, we introduce a MIP model and implement a tailored Adaptive Large Neighborhood Search (ALNS) algorithm. Through extensive computational experiments utilizing real-life instances, our findings consistently demonstrate that ALNS yields near-optimal solutions and substantially enhances operational metrics by approximately 30%.

4 - A Scheduling Algorithm for Drone-Sharing

Ulrike Ritzinger, Bin Hu, Hannes Koller, Peter Widhalm

Drones are becoming increasingly popular for various tasks in different domains, such as assessing infrastructure damage, conducting surveys, and responding to emergencies. Typically, users of drone services enter individual contracts with a service provider for each order who provides the necessary technical equipment (drones, sensors, pilots, operating license). With the growing number of users, it has become inefficient to perform individual orders independently because their synergies are not considered.

Therefore, a new business model called the drone-sharing economy is emerging. Sharing drones, equipment, pilots, and data among multiple users from a particular region can significantly increase efficiency. This is made possible by holistic and cross-task mission planning with a high degree of automation where the challenge lies in optimizing the schedule of all orders to maximize their synergies while adapting to dynamic conditions such as the weather and new or changing orders.

We propose a scheduling algorithm that employs variable neighborhood search to generate a rolling-horizon schedule for both drones and pilots. Due to the various requirements of the orders such as operational area, time windows, and others, multiple flight plans are generated. The goal is to maximize the number of orders completed by selecting the most fitting flight plan while considering constraints like drone and pilot compatibilities, data quality, and changing weather conditions.

1 - Practical skills: Knowledge-sharing tutorials -1-

Making An Impact, Jonas Witt, Sander Van Aken

Expand your skills with these two 45' practical sessions: Building And Sharing Apps: An Introduction To Streamlit, and OR Goes Kubernetes: How To Run Long Running Optimization Jobs In The Cloud

(i) Building And Sharing Apps: An Introduction To Streamlit (Sander van Aken, Flixbus) Making impact with OR often requires an end-user or other stakeholders to interact with the models and algorithms you build, or with its outcomes. With interactive applications, we can leverage the true power of human-machine collaboration, e.g. by letting users guide your optimization model with their knowledge, or enabling them to explore multiple solutions. Developing fully-fledged front-end applications - or even discovering what is the right thing to develop - can however take up a tremendous amount of time. For some analyses or projects, it is not even worth the effort. The Python-based framework Streamlit could be your new companion in these endeavours. In this tutorial, we demonstrate how we can use it to quickly develop a first version and iterate on that.

(ii) OR Goes Kubernetes: How To Run Long Running Optimization Jobs In The Cloud (Jonas Witt DHL) While response time often matters in OR applications, in many cases it does not (think network design, tactical capacity planning, ...). In these use cases, model usage will be dispersed over time and not warrant the constant provisioning of a high-end compute resource at all times. In our OR applications at DHL Group, we experienced that this often led to some boilerplate functionality that had to set up across use cases: Sequencing of requests, automatic deployment of workloads, status monitoring, result retrieval, etc. In this tutorial we will share what we are currently building to replace boilerplate code with a scalable, modern tech-stack to support the deployment of tactical decision support tools.

How to support complex decisions. Negotiating the trade-off between Social, Environmental and Economic values 1

Stream: Multiple Criteria Decision Analysis
Invited session

Chair: *Alessandra Oppio*

Chair: *Marta DellOvo*

Chair: *Giulia Datola*

1 - A Diachronic Index for Assessing Landscape Economic Value

Sebastiano Barbieri, Marta Bottero, Caterina Caprioli, Giulia Datola

Landscape, as an environmental asset, can be evaluated using various techniques. One of the most common approaches is to use a system of indicators, to take account of the different characteristics that make up the landscape. Indicators alone cannot provide a comprehensive overview of territories. In addition, territories are characterised by dynamics and characteristics that change over time, requiring a diachronic analysis. Within this context, the present work proposes a Multi-Criteria Analysis (MCA) to provide a synthetic index capable of describing the economic value of the landscape. For the elaboration of that index, many data referring to various aspects and different periods are considered. Specifically, the current state of the landscape is compared with past recognized conditions, taking into account the dynamics of agriculture, tourism, real estate market and forest dimensions over time. The aim is to provide systematic information useful to support decision-makers and policymakers in the protection, conservation, and planning of the landscape at a regional scale. To test the selected set of criteria and the construction of the index, the present study applies the proposed method to the Piedmont region in north-west Italy, because of its diversity of landscapes, ranging from mountains and hills to plains.

2 - Optimising NbS Allocation to Negotiate the Trade-off Between Ecosystem Service Supply and Demand in Urban Areas

Francesco Sica

The Ecosystem Services (ES) refer to a decision-making condition in which the existence of many and different aspects (regulatory, provisioning and cultural) imposes a reciprocal trade-off rules that gives some greater legitimacy to others. Dealing with ES in a complex decision-making system encourages evaluations to achieve a short-medium-long-term equilibrium between ES supply and demand in the social, economic, and environmental context of reference. This is especially exacerbated in the urban settings, where types guidelines of trade-offs alongside those of ecosystem services take action, e.g. in cases to design and program urban land use via Nature-based Solution

(NbS). It intends to present an integrated approach based on multi-criteria logics, with the goal of minimizing the ecosystem service supply and demand trade-off for Nbs allocation across urban areas. The approach's substance lies in the formalization of an optimization algorithm based on ES accounting and the AHP protocol, as well as the financial, economic, environmental, social, and cultural constraints that aid in the case-specific personalization of urban planning and environmental NbS design strategies. An description of the Italian case study, which was examined testing the proposed optimization algorithm, rounds up the presentation.

3 - Prioritizing Nature-Based Solutions for Sustainable Water Management: A water utility case study in São Paulo, Brazil

Francisco Silva Pinto

As the global demand for sustainable water management solutions continues to escalate, the prioritization of Nature-Based Solutions (NBS) has emerged as a critical strategy for addressing water challenges. This study presents a comprehensive approach to prioritize NBS using Multiple Criteria Decision Analysis (MCDA) within the context of a water utility case study in São Paulo, Brazil. São Paulo, a megacity grappling with water scarcity and quality issues, serves as an ideal setting to explore the effectiveness of NBS in mitigating water-related challenges. Through an integrated MCDA framework, various criteria such as environmental impact, total cost, integration with existing infrastructures, flexibility, simplicity and transparency, supply safety, among others are evaluated to assess the suitability of NBS alternatives. The study employs a participatory approach involving stakeholders from diverse sectors to ensure transparency and inclusivity in the decision-making process. By synthesizing qualitative and quantitative data, the MCDA facilitates the identification of optimal NBS interventions tailored to the unique socio-environmental context of São Paulo. The findings of this study not only contribute to advancing knowledge on NBS prioritization methodologies but also offer practical insights for water utilities and policymakers seeking sustainable solutions to water management challenges in urban settings.

4 - Enabling the Circular Economy in Agriculture: A Methodological Proposal of Social Multi-Criteria Evaluation to Represent Multiple Values

Giulia Datola, Eleonora Catellani, Federica Ciccullo, Niso Randellini, Alessandra Oppio

The ecological transition to enhance a sustainable and circular approach to resources is the current global challenge, as well as the complex decision-making process that the global community is called upon to manage. In this context, the agricultural and food production sector is trying to pass from a linear resource consumption to a circular management of resources, through the adoption of different circular technologies. Due to the high level of complexity, and multidimensional effects, this transition process is facing many challenges and issues. One of the main observed challenges concerns stakeholders' involvement and the identification of the different values engaged within this transition process. This issue is mainly due to the different levels at which the decision problem of implementing the circular economy paradigm in agriculture should be addressed. According to this challenge, this research is interested in providing a methodological framework to apply the Social Multi-Criteria Analysis to address the implementation of circular technologies in agriculture within stakeholders' perspectives, values, and probable coalition. The main objective is to provide a decision support system able to manage and represent the complexity of the transition to the circular economy paradigm of agriculture. The challenge of the research is using evaluation as a communication, engagement and enabling tool to address innovation according to multidimensional values.

DEA and stochastic models

Stream: Data Envelopment Analysis and its Application
Invited session

Chair: Andreas Georgiou

1 - A hybrid bi-level DEA model under uncertainty conditions

Eleni-Maria Vretta, Andreas Georgiou, Konstantinos Kaparis, Kyriakos Bitsis, George Paltayan, Fenia Mavrodi, Emmanuel Thanassoulis

The efficient allocation of limited resources along with profit optimization play a crucial role in large enterprises and organizations. Given the continuous fluctuations in data and the lack of historical data, managers seek an optimal dynamic strategy to maximize the profits and at the same time keep organizational efficiency at satisfying levels. In some business contexts a central decision-making unit might govern management decisions over multiple subordinate decision-making units and in this study, we investigate efficiency in a stochastic framework using a combined bilevel - DEA approach. We define discrete scenarios with some occurrence probabilities to assign values to uncertain parameters thus enabling decision readjustments upon the realization of each scenario, contributing to an enhanced overall strategy. The proposed approach involves an upper-level problem that handles organizational effectiveness (i.e. profit) and a lower-level problem that handles subDMUs' efficiency. Input and output bounds are also used in the same sense as assurance regions along with lower bounds on subDMUs' efficiencies. The presentation concludes with applications in the banking or healthcare sector.

The research project was supported by the Hellenic Foundation for Research and Innovation (H.F.R.I) under the "2nd Call for H.F.R.I. Research Projects to support Faculty Members & Researchers" (Project Number: 3154).

2 - Stochastic Dynamic Cost-Efficiency: Development of a Chance-Constrained Data Envelopment Analysis (CCDEA) model with Window Analysis and Optimal Control Principles

Paulo Nocera Alves Junior, Ali Emrouznejad, Wilfredo Yushimito, Carlos Monardes, Isotilia Costa Melo

This study presents the development of an innovative approach to Stochastic Data Envelopment Analysis (SDEA), considering Chance-Constrained Programming (CCP), Window Analysis (WA), and Optimal Control Theory (OCT) principles in a framework with time and probabilistic constraints. Besides, it involves the average values, covariance matrices and probabilities of each window over time. By incorporating dynamic elements from recent advancements, such as intermediate variables (inventory costs), this model examines the total cost efficiency based on the relationship among variables, such as costs of goods sold (related to the demand), costs of purchased (or produced) products (related to the production or ordered quantities), and inventory costs (related to the initial and final inventories of the period), along with their uncertainties. This enables a dynamic and stochastic evaluation of the cost efficiency of inventory control systems. OCT principles are applied to link variables and introduce dynamics into the system, whereas CCP and WA are utilized to construct temporal windows and integrate their stochastic properties. The result is an SDEA model grounded in OCT principles to assess the total cost efficiency of the control systems from Decision-Making Units (DMUs), as in the retail sector, over time and considering uncertainties. This approach considers real-world conditions, thereby improving analysis and contributing to the development of more efficient control systems.

3 - Stochastic multi-period and multi-stage efficiency measures

Shiang-Tai Liu

Many uncontrollable factors will affect company operations. In addition, the collected data is often snapshot observations, and if collected earlier or later, the values may differ. A company's inputs and outputs over time are thus stochastic variables. Several approaches have been proposed to deal with stochastic observations in efficiency measurement, including stochastic frontier analysis and chance-constrained programming. Conventionally, each DMU's input and output variables are assumed to be independent. This assumption is unrealistic because DEA requires isotonicity, which implies that the outputs correlate with the inputs. Ignoring this correlation will produce misleading results. In a network system, the merit of efficiency decomposition is that a relationship between the system and division efficiencies is obtained, based on which the division affecting the entire system's performance the most can be identified. When the observations are stochastic variables with multivariate normal distributions, they can be transformed into a variable with a standard normal distribution. In addition, only looking at a single time efficiency may lose the general picture of the overall performance for a multi-period. This paper aims to develop a model to measure the efficiency of DMUs with several divisions performing specific operations over a time period. This model is able to handle multi-period stochastic data and decompose the system's efficiency into division efficiencies.

4 - Planning methods using Data Envelopment Analysis and Markov Systems

Andreas Georgiou, Emmanuel Thanassoulis, George Tsaples, Konstantinos Kaparis

This paper addresses contexts in manpower or in the progression of chronic diseases. It uses the notion of a cohort whose members advance through various states over time (e.g. employees or patients). The aim is to steer the system towards a desired state, or set of states, through interventions made by recruitment or treatments which are evaluated on their capacity to achieve this goal in fixed or free time control settings. The presentation is based on a modelling framework, which blends DEA with Markov Chains in radial and additive models. The Markov process offers a set of equations that can be used to describe the movement of entities through time in a hierarchical system (e.g. illness states) and makes possible the investigation of interventions in order to guide the system towards a desired future structure. A given set of possible policies (e.g., new treatments used in a health system) are treated as DMUS at each stage and various models, including single or two-stage configurations with recruitment Decision Making Units (DMUs), are presented in single or multiple targeting environments. The paper concludes by deliberating on the merits and constraints inherent in these models.

The research project was supported by the Hellenic Foundation for Research and Innovation (H.F.R.I) under the "2nd Call for H.F.R.I. Research Projects to support Faculty Members & Researchers" (Project Number: 3154).

Lot-sizing with industrial applications I

Stream: Lot Sizing, Lot Scheduling and Production Planning
Invited session

Chair: Rui Borges Lopes

1 - A Mathematical Model for the Optimization of a Shoe Injection Machine

Eliana Costa e Silva, Adelaide Cerveira, Norberto Jorge Gonçalves, Rui Borges Lopes, Conceição Nogueira

The present study introduces a novel mathematical model developed to address a challenge posed at the 174th European Study Group with Industry, by a prominent footwear company. The objective is to design a model that optimizes the utilization of shoe injection machines, machines used to produce a diverse range of shoe models and colors of

shoes across up to 15 different sizes. The primary goal is to enhance production efficiency throughout the manufacturing process, including the preparation and finishing phases. To tackle this complex optimization problem, an integer programming model has been developed. This model is designed to minimize setup times associated with changes in color, model, and size, thereby streamlining the production process. Moreover, considering the substantial investment involved, the model also takes into consideration the limited availability of molds. In this work, some preliminary findings derived from both academic and real-world instances will be presented. Additionally, ongoing efforts and future enhancements aimed at refining the efficacy of the proposed model will be outlined. This work has been partially supported by national funds through FCT - Fundação para a Ciência e Tecnologia, under the project UIDB/04728/2020.

2 - Optimizing Shoe Injection Machine Utilization: A Heuristic Approach

Rui Borges Lopes, Adelaide Cerveira, Eliana Costa e Silva, Norberto Jorge Gonçalves, Conceição Nogueira

In the 174th European Study Group with Industry, a footwear company put forward a challenge that consisted of optimizing the utilization of one of its shoe injection machines. This machine, capable of high cadence, has the versatility to produce various types of shoes in different colors and sizes. In order to increase its utilization, the company wanted to reduce setup times associated with mold and color changes, as it had a significant impact. To this end, it was to be determined the production sequence that would lead to the highest throughput in the given planning horizon.

To tackle this problem, new constructive and improvement methods were developed and incorporated into a metaheuristic, specifically the Greedy Randomized Adaptive Search Procedure (GRASP). The GRASP was tested using both an academic and a real-world instance. For the academic instance, results were compared with an exact approach, while for the real-world instance a comparison was made with the actual planning of the company. This presentation will discuss the obtained results and will address some of the managerial insights gained from this study.

3 - An optimization model for the sequencing problem with dependent and asymmetric setups: an application in the chocolate milk industry.

Carlos Ernani Fries, Yasmin Izzo Choucair

Production planning problems have been extensively explored in the literature due to their wide-ranging applications and the necessity to adapt them to evolving technologies. Optimization techniques for production sequencing have garnered significant attention among companies striving for sustained high levels of production efficiency to compete effectively in both domestic and international markets. This study aims to propose and implement an optimization model that outlines production sequencing plans tailored to the chocolate milk industry. It takes into consideration the characteristics of the job shop environment, including asymmetric and sequence-dependent setup times. These challenges pose computational hurdles due to their high combinatorial complexity, particularly when managing many products and machines. In this study, three main features are emphasized due to the quantity and diversity of SKUs they produce. Such diversity often leads to frequent line stops for machine configuration, resulting in low productivity indicators. The proposed model integrates mathematical programming with heuristic approaches to address subproblems and minimize total setup time. Applying the model using real data resulted in a noteworthy 24% reduction in the average total setup time observed in the company under study.

4 - Flexible production planning using BoM structure and time-varying demand objectives

Yasmin Roshandel

This research addresses the production planning challenges inherent in the bicycle manufacturing industry, focusing on the optimization of bicycle production with demand deadlines. Our approach uses a time-dependent bill of material (BoM) structure, considering the availability of components to meet daily production capacities, guided by

forecasted monthly demand objectives. The planning horizon spans six months, requiring solutions that balance quality and computational complexity. Leveraging techniques from integer linear programming and heuristics, we aim to efficiently generate production plans for different types of bicycles composed of many different components. Our methodology uses a multi-ranking system to select bicycles to produce so that we balance demand, producibility, and planning complexity. This strategy fits with the unpredictable nature of the bicycle market, enabling quick responses to updated demand forecasts while maintaining planning robustness.

Monday, 12:30-14:00 - Room: M2 (building: 101)

Retail Inventory Management II

Stream: Retail Operations

Invited session

Chair: *Heinrich Kuhn*

1 - The Optimal Policy for a Cyclic Capacitated Lost Sales Inventory

Ludwig Brieditis, Peter Berling

Determining optimal replenishment of brick-and-mortar retail stores is a challenging problem. Based on experience from a large north European grocery store, these retailers typically face a non-stationary demand with a recurrent periodic pattern where excess demand is lost. Moreover, replenishment opportunities are limited by a weekly schedule with limited transport capacity allocated to each store.

The optimal replenishment decisions for a store in this setting is previously unknown. We show that a periodic modified base-stock policy is optimal, i.e. ordering so that the resulting inventory is as close as possible to the optimal base-stock level of the period by modeling the problem as a Markov Decision Process. It is straightforward to use the model to find the optimal base-stock levels. A numerical study shows the resulting cost increases when using solution methods that disregard some of the setting characteristics, e.g. non-stationary demand, limited capacity, lost sales.

Efficiently solving this problem is important not only to minimize the cost at the stores but also to evaluate various planning decisions, e.g. scheduling and routing, in the greater distribution network.

2 - Multi-Echelon Inventory Optimization: A Case Study considering real-life constraints and uncertainties

Philip Mårtensson, Joakim Andersson, Johan Lidvall, Johan Marklund

This paper presents an investigation into multi-echelon inventory optimization, emphasizing the integration of real-life constraints and uncertainties. By considering a case study for spare parts in the automotive industry, derived from practical inventory management scenarios, we address the complexities inherent in supply chain dynamics. Through our analysis, we demonstrate the efficacy of our proposed approach in enhancing inventory control across multiple echelons while underscoring the importance of considering real-world factors such as lead times, demand variability, and capacity constraints. Another aspect that is considered, in a distribution system with mixed ownership of the retailers, is the implementation feasibility of transitioning from a traditional single-echelon inventory control system, requiring extensive stakeholder management and buy-in. The findings bridge the gap between practitioners and researchers in this area, offering valuable insights into future research of applying multi-echelon theory and techniques in dynamic supply chain environments.

3 - Inventory control of end-of-sales-life products with integrated online and offline sales channels

Ben Lowery, Anna-Lena Sachs, Idris Eckley

In a business with integrated online and offline storefronts, the management and control of stock for end-of-sales-life products facing uncertainty and decline in demand poses important operational challenges. The retailer sells items through its stores and its warehouse. The stores satisfy demand from its available stock, while the warehouse fulfills online orders as well as a proportion of excess customer demand if the stores did not have enough stock on hand; with remaining unsatisfied demand at the store becoming lost-sales.

We develop a two-echelon divergent, periodic-review inventory model, with partial lost-sales at the store level, to determine order quantities during the end-of-sales-life period. We solve small instances to optimality using dynamic programming techniques. Due to the curse of dimensionality, we develop novel heuristics to make ordering decisions that balance accuracy and interpretability for larger instances.

4 - The flexible shelf space refilling problem

Sandra Zajac, Moritz Hundhammer, Michael Sternbeck, Heinrich Kuhn

Shelf space is a fundamental resource in retail and thus it is vital to manage it efficiently. In traditional shelf space planning, the number of facings is defined in advance and it is assumed that this number will not be changed during the operational replenishment process in the store. In operational practice, however, it is often beneficial to deviate from this tactical shelf plan to reduce in-store replenishment costs. Increasing the facing number of a product decreases the required effort for replenishing this product as more items fit in the showroom shelf space. However, due to limited shelf space, it will be necessary to reduce the facing number of other products which in turn may lead to additional in-store replenishment effort. Adapting the shelf layout further causes rearrangement costs, most notably facing elimination and shifting costs. This paper introduces the flexible shelf space refilling problem in which total in-store replenishment and rearrangement costs are minimized. We illustrate in detail the current process of adapting the number of facings during the refilling process and give some empirical insights to demonstrate the practical relevance of the problem. To provide decision support, a first seminal mathematical model is presented and its suitability to improve the operational shelf space refilling process is demonstrated based on a first case study. Lastly, we give an overview on possible future research directions in this new area of research.

Quantitative methods for systemic and climate risk

Stream: Risk management in finance

Invited session

Chair: *Gabriele Torri*

1 - On the measure of ambiguity on financial markets

Hachmi Ben Ameer, Zied Ftiti, Wael Louhichi, Jean-Luc Prigent

The impact of ambiguity on financial markets continues to be a debated topic. Like most decisions in life, we face ambiguity, which is the uncertainty about true probabilities. However, this aspect of uncertainty is often overlooked, despite its widespread presence in financial markets and the significant impact it can have. A prime example of extreme ambiguity is a financial crisis, where substantial uncertainty arises and investor behavior is markedly influenced. Therefore, understanding the influence of ambiguity on financial markets is crucial. This paper introduces two fundamental statistical tools for measuring

ambiguity in financial data: the Wasserstein metric and the Kullback-Leibler divergence. These tools assess how close or distant probability distributions are from an expected probability distribution. These criteria are particularly useful for measuring ambiguity during financial crises, especially in multi-dimensional cases. We conduct empirical analysis using major financial indices, such as the S&P 500, Nikkei 225, Eurostoxx 600, and DXY index, covering the period from January 2000 to December 2022. The findings have significant practical and operational implications for portfolio allocation. It is crucial to consider uncertainty regarding the true values of financial parameters when determining the optimal portfolio profile

2 - Pricing synthetic CDOs under infectious defaults with immunization

Gabriele Torri, Gianluca Farina, Rosella Giacometti

This work introduces a recursive algorithm for the portfolio loss distribution similar, in spirit, to the one commonly used for CID (conditionally independent) models. We model default events under a contagion mechanism which is the result of two independent components: an infection attempt generated by defaulting entities and a failed defence from healthy ones. A recursive algorithm for the calculation of the portfolio loss distribution is presented that shows a good level of computational tractability even when an heterogeneous set of names is considered. We apply it to the pricing and hedging of CDO instruments and compare its performance to the standard one factor Gaussian model.

3 - ESG enhanced tracking portfolio with quantile regression

Marco Bonomelli, Rosella Giacometti

The purpose of this paper is the formulation of an enhanced index replication model with second order stochastic dominance constraints. The replicating portfolio is constructed minimizing an asymmetric deviation measure via quantile regression. According to the investor's risk aversion preference, the resulting linear optimization problem can be solved for different quantiles. In order to take into account the increasing attention to ESG issues, the strategies can be enhanced, via hard and soft constraints, focusing on the sustainability of the replicating portfolio. The performance of the optimal portfolios are tested both in-sample and out-of-sample, and are compared to the solutions of well-known models.

4 - Surface Measures of Tail Dependence and Climate Change

Davide Lauria

Systemic financial risk refers to the situation in which failures or disturbances in one part of the financial system can spread rapidly and extensively, resulting in significant disruptions to the broader economy. Measuring systemic financial risk is a complex task that typically involves various quantitative and qualitative indicators. Examples include the Systemic Risk Index (SRISK), Conditional Value-at-Risk (CoVaR), and Financial Stress Index (FSI). Such measures are closely related to tail dependence measures, which are introduced to quantify the extent of dependence between extreme events of a couple of random variables. The scope of this research is to provide insight into the possible connection between the risk factors behind climate change and the strength of systemic risk among European companies. To achieve this aim, we first introduce a systemic risk measure based on a recently proposed coefficient of tail dependence which is derived from surface integrals. We then compare the results with existing research. Subsequently, we dynamically relate such measures to the evolution of a set of climate change risk factors.

Multi-objective Combinatorial Optimization

Stream: Combinatorial Optimization

Invited session

Chair: Trine Krogh Boomsma

1 - Sensitivity analysis of the cost coefficients in multi-objective integer linear optimization

Britta Efkes, Kim Allan Andersen, Trine Krogh Boomsma, Nicolas Forget

We consider sensitivity analysis of the cost coefficients in multi-objective integer linear programming problems and define the sensitivity region as the set of simultaneous changes to the objective function coefficients for which the efficient set and its structure remain the same. In particular, we require that the component-wise relation between efficient solutions is preserved and that inefficient solutions remain inefficient. We present necessary and sufficient conditions on permissible changes that satisfy the defined properties. In this talk we concentrate on changes to a single objective function coefficient and show that the sensitivity region is a convex set, i.e., an interval. In order to avoid going through all pairs of feasible and efficient solutions, we introduce further properties that identify inefficient solutions that remain inefficient whatever the change is. Based on this, a subset of the inefficient solutions can be excluded from consideration. More specifically, we prove that it suffices to inspect the inefficient solutions of a q -objective problem that are efficient in one of two related $(q + 1)$ -objective problems, in the case of only one change. Computational experiments with multi-objective binary and integer knapsack problems demonstrate the general applicability of our technique.

2 - Generator sets for Minkowski Sums - Theory and Insights

Mark Lyngesen, Sune Lauth Gadegaard, Lars Relund Nielsen

In this presentation we consider a class of multi-objective optimization problems known as Minkowski sum problems or Pareto sum problems. Pareto sum problems are multi-objective optimization problems with a decomposable structure where the (global) Pareto set (the nondominated points of the feasible objective space) can be described as the Pareto set of the Minkowski sum of several (local) Pareto sets obtained from subproblems. Much research has been done on efficiently filtering for the set of (global) Pareto sum given several known (local) Pareto sets. In some cases, only subsets of the (local) Pareto sets are required for generating the global Pareto sum. As such, if a subproblem solution does not contribute in generating the (global) Pareto sum, then the computational effort spent on finding the solution is effectively wasted. For this reason, we investigate how small a subset of the Pareto optimal solutions from subproblems is necessary to describe the Pareto sum. Furthermore, we investigate when unnecessary Pareto optimal solutions exist in the subproblems and how to identify them. For this purpose we propose so-called generator upper bound sets, which can be used when solving the subproblems to exclude some unnecessary solutions. If and when these non-generating or unnecessary Pareto optimal solutions can be identified and excluded, the computational burden of identifying a generating subset of Pareto optimal solutions of a subset may be substantially reduced.

3 - On the extension of branch-and-bound methods for mixed-integer linear programs

Nicolas Forget, Sophie Parragh

In the recent years, a lot of attention was given to branch-and-bound techniques for solving pure integer linear programs with an arbitrary number of objectives. Significant progress and contributions were made. On the other hand, the efficiency and practicality of branch-and-bound methods for bi-objective mixed-integer linear was shown through a variety of works in the past decade. Intuitively, the next step is to address mixed-integer linear programs with three or more

objective functions. Again, linear-relaxation based branch-and-bound frameworks appear to be the methods of choice because of the continuous nature of some variables. Unfortunately, due to the complex structure of the non-dominated set of such problems, straight-forward extension of existing branch-and-bound frameworks to solve multi-objective mixed-integer linear programs is not possible. In this talk, we identify some of these obstacles (representation and navigation of the non-dominated set, update of the upper bound set, dominance test, etc.), and present various solutions we explored to address these issues. Moreover, we highlight implementation-related and performance-related difficulties, and conclude with future works.

4 - Multi-objective Optimization of Retrial Machine Repair Problem with Warm Standbys and Working Vacation

Kuo-Hsiung Wang

Abstract: This study investigates the retrial machine repair problem with warm standbys and working vacation, in which the server works with different repair rates rather than completely halting the repair during a vacation period. It is assumed that the server begins working vacation when the system is empty. When a failed machine finds that the server is idle upon arrival, it is immediately repaired by the server. If the failed machine finds that the server is busy upon arrival, it leaves the repair facility to join the retrial orbit and attempts repair again. The failure, repair, vacation, and retrial times are assumed to be exponentially distributed. A matrix analytic method was used to compute steady-state probabilities and several system performance measures. A multi-objective model for the cost and expected waiting time was derived. The epsilon-constraint method and non-dominated sorting genetic algorithm were used to identify and compare the Pareto optimal set and make comparisons. The Pareto front set was obtained and illustrated to improve the quality of decision making for system engineers.

Chair: Stella Nadine Steidl

1 - "Pig-Electricity Synergy" System in Sustainable Energy Development

Huang Sun-weng., Jian-hua Xia, James Liou, Gwo-Hsiung Tzeng

In the current scenario where energy crises are increasingly evident, the development of renewable energy has become a crucial pathway towards achieving sustainable development. The "Pig-Electricity Synergy" system emerges as an advanced energy solution, seamlessly integrating pig farming and solar energy storage technologies. The core advantage of this technology lies in its integrated application of solar energy and storage technology, forming a diverse and reliable energy management system. The uniqueness of the "Pig-Electricity Synergy" system lies in its successful realization of the integration of solar energy and pig farming, enhancing energy reliability through collaborative operations and significantly mitigating system risks. The resulting diverse and flexible energy management system not only meets the escalating demands of energy but also contributes to enhancing the resilience of the overall energy framework. This study employs DEMATEL analysis and ISM modeling to delve into the pivotal role of the "Pig-Electricity Synergy" system in sustainable energy development. Through a comprehensive analysis of the system's technology, diverse energy integration, and flexibility, the research aims to provide tangible and viable solutions for sustainable energy development. The application of DEMATEL and ISM contributes to a deeper understanding of the inherent relationships within the system, offering profound insights for sustainable development decision-making.

2 - Assessing weather resilience of the Swiss electricity system in 2035 via spatially-explicit modeling

Giacomo Rubino, Evelina Trutnevyte

Recent studies point to weather dependency of renewable electricity sources as a limitation to the system's resilience in case that high shares of renewable electricity are reached. The impact of weather is, however, highly variable in space and time, making high-resolution resilience assessment a necessity. This study aims to test Swiss electricity system in 2035 against 25 years of historical weather conditions that affect hourly profiles of solar photovoltaic (PV), wind power, and hydropower, as well as electricity demand for heating. In particular, four strategies of locating new solar PV, wind plants, and heat pumps in Switzerland are investigated, based on (i) continuation of current trends, (ii) technical potential, (iii) population, and (iv) minimum system cost approach. The analysis is conducted using a technology-rich cost-optimization model EXPANSE that generates scenarios at a temporal resolution of three hours resolution and a spatial resolution of Swiss 2136 municipalities. Six electricity system resilience indicators are then calculated to compare the four strategies: equivalent availability factor, energy import dependency, diversification of energy supply, decentralization index, renewable electricity generation, and self-sufficient electricity supply.

3 - GIS-based optimization tool for green hydrogen integration in cities: A comparative case study of New Zealand and German cities

Stella Nadine Steidl, Jannik Haas, Rebecca Peer, Alaa Alhamwi, Alejandro Zabala Figueroa, Wided Medjroubi

We introduce the GIS-based optimization tool FlexiGIS-H2, applied to urban areas in both New Zealand and Germany to identify the potential for hydrogen to aid the energy transition within cities. Based merely on open-source datasets, we connect existing urban energy infrastructure, electricity generation and hydrogen production potential and the specific demand of a given city. Land use and building types are used to calculate electricity demand, and available areas are analysed to estimate the potential electricity generation from solar and wind resources, alongside the potential production of green hydrogen. Through cost-minimization, we optimize storage scenarios including batteries and green hydrogen, and solve for the most techno-economic solution to meet electricity and hydrogen demand for urban applications.

In this work, we present the model FlexiGIS-H2 applied to the cities Auckland, Christchurch, Karlsruhe, and Oldenburg, in New Zealand and Germany. Here, we delve into the application of FlexiGIS-H2, our modelling outcomes for different cities, and ongoing developments aimed at supporting decision-making for future energy system planning in urban areas. The resulting hydrogen portfolio and residual energy scenarios, and the optimisation of hydrogen as a flexibility option in urban settings, can be used as inputs to national capacity expansion tools, to provide local detail often lacking at the national level.

4 - Assessing the performance of optimized energy communities under uncertainties

Nathalie Frieß, Ulrich Pferschy, Joachim Schauer

Renewable Energy Communities (RECs) can provide a useful contribution to the decarbonization of the energy sector if they bring about an actual change in physical electricity flows, i.e., if they lead to an optimized use of locally produced energy. Main tools for reaching this objective are load shifting and intelligent battery management. Based on forecasts of production and consumption profiles, the associated operational decisions can be optimized with the goal of improving the overall performance of the community. The strong interdependence between the community members' individual resources prohibits the use of simple heuristic decision rules for this purpose. As actual conditions may well deviate from the forecasts used for optimization, not all optimized decisions will yield the intended outcome. Therefore, we developed a Model Predictive Control inspired planning framework that comprises an optimization model and a simulation model. Using the most recent available short-term forecasts as input, the optimization model is solved for a planning period of 96 time steps. The computed optimization output for the upcoming time step then serves as input for the simulation model, which models the actual real-world outcome

of the planning decisions for the current time step. The introduced framework can be used to generate realistic performance measures and to reach a better understanding of the benefits of optimization-based decision-making in RECs.

1 - A Dynamic Electric Dial-a-Ride Problem with Optional Service Upgrades

Christian Ackermann, Julia Rieck

The demand for sustainable urban mobility has surged with the increasing focus on climate protection. Consequently, ride-sharing services powered by electric vehicles (EVs) are gaining unprecedented attention. While EVs increase environmental benefits, they also present challenges due to the scarcity of charging infrastructure. Moreover, standard dial-a-ride settings, with their broad time windows and lengthy ride times, fall short of the service quality needed to persuade the broader public to switch from private cars.

Our study tackles a special Dial-a-Ride Problem (DARP), deploying EVs to meet dynamically incoming customer requests within a framework of limited charging stations and non-linear charging functions. To enhance appeal and utility, customers can opt for higher-priced premium options, such as non-shared rides, reduced ride time, or reduced delay at drop-off. The service provider must immediately decide whether to fulfill these premium requests or decline them and execute the customer request with standard service.

We conduct a comparative analysis of various charging strategies, evaluating their efficacy and relative impact on operational quality. Moreover, we tailor routing and scheduling strategies to accommodate the mixed standard and premium request nature. In this way, environmental considerations of EV usage are combined with enhanced service quality through premium options, resulting in a pragmatic approach to upgrading urban mobility.

2 - The Dynamic Electric Dial a Ride on a Fixed Circuit

Rotem Zohar, Ohad Eisenhandler, Kris Braekers, Mor Kaspri

Autonomous vehicles are set to transform urban mobility by embracing mobility as a service, presenting opportunities for cost reduction, diminished vehicular ownership, and enhanced road safety. Despite these advantages, shared autonomous mobility services face harsh restrictions, often confining them to fixed circuits and schedules. In the electric dial-a-ride problem on a fixed circuit (eDARP-FC), a fleet of electric shuttles provide on demand services while performing multiple laps on a designated circuit consisting of recharging depots and passenger stations. While such an operation has been investigated in the literature in a static setting, the challenges of a dynamic context have not been addressed so far. Therefore, we focus on the implications of dynamically arriving requests on both modeling aspects and solution techniques. This setting, requires making iterative decisions on request acceptance, assignment to vehicles and battery management. The objective function consists of several weighted components, including the number of accepted requests, users' total journey time, and the total number of vehicle laps. Our approach explores several online policies, employs an event-based simulation framework for high-resolution representation, and integrates a reinforcement learning model to solve large-scale instances effectively. The goal is to derive explainable dynamic operational policies that provide better balance between operational costs and the quality of service.

3 - Mixed-integer linear programming formulations for the line-based dial-a-ride problem

Marie Schmidt, Kendra Reiter, Daniela Gaul, Michael Stiglmayr

On trajectories with low demand, scheduled busses are often not efficient. If operated frequently, they may be able to capture a significant fraction of overall demand, but often run with few passengers on board or even empty. If frequencies are decreased, the service becomes inconvenient for passengers, and demand will further decline. On-demand ridepooling has been proposed as an alternative. However, while high service levels can be achieved if enough capacity is provided, such services are inefficient if demand is not properly pooled or if a significant amount of deadheading occurs. For this reason, we propose an intermediate solution where services are line-based but not schedule-based. In the line-based dial-a-ride problem (liDARP) we study the following optimization problem: Given a sequence of stops, a number of vehicles, and a set of stop-to-stop transportation requests with time windows for pickup and delivery, assign services to the vehicles and passengers to the services such that each service visits the stops in the indicated sequence, and passengers are transported from origin stop to destination stop by the service they are assigned to, while minimizing a weighted sum of transported requests, km driven, vehicles used, and car km saved. We compare three MILP formulations of the liDARP, one that encodes assignment of vehicles and passengers to services, one that relies on the 3-index formulation for the general DARP, and one event-based formulation.

4 - The Multi-objective Dial-a-Ride Problem

Michael Stiglmayr

Ridepooling applications ask for fast computation of vehicle routes and passenger allocations. This so-called dial-a-ride problem (DARP) has to compromise between the efficiency of the ridepooling system (e.g., routing costs) and customer satisfaction (excess ride time and the number of served requests), subject to time window constraints, vehicle load constraints, and maximum ride time constraints. In this talk, we present a multi-objective variant of DARP and investigate the trade-off between the objectives of the service provider and those of the customers.

Moreover, we present a tight mixed-integer linear programming (MILP) formulation for the DARP by combining two state-of-the-art models into a novel location-augmented-event-based formulation. The formulation is tight in the sense that, if time windows shrink to a single point in time, the linear programming relaxation yields integer (and hence optimal) solutions. Strong valid inequalities and lower and upper bounding techniques are derived to further improve the formulation. We then demonstrate the theoretical and computational superiority of the new model: First, we prove that the new formulation has a tighter linear programming relaxation than the two-index formulation. Second, extensive numerical experiments on benchmark instances show that computational times are on average reduced by 49.7% compared to the state-of-the-art event-based approach.

■ MC-55

Monday, 12:30-14:00 - Room: S02 (building: 101)

Airline Applications I

Stream: Transportation
Invited session

Chair: [Christian Truden](#)

1 - On airline frequency competition for routes linking emerging airports

Amit Bardhan

We analyse a scenario where two competing airlines, are considering new routes to emerging airports. These airlines can design either direct

routes or connect passengers via their respective hubs. The total market size for a route is influenced by two key factors: flight frequency and network connectivity, while passengers prefer direct flights over those with layovers. An airline's revenue on a route hinges on both the overall market size and its capacity share. Therefore, each airline faces a strategic decision regarding the optimal frequency of flights to allocate on each new route. The cost of deploying capacity on a route encompasses several factors: direct aircraft operating costs, airport fees (landing, gate usage), and passenger handling expenses. Airport fees are typically higher at major hubs, which may also impose slot restrictions due to capacity constraints. Airlines' objective is to maximize their profits. To analyse this frequency competition, we propose a game-theoretic model similar to developed in Wang et al. (2022). By analysing the model's equilibrium, we obtain insights, such as the conditions under which airlines might reallocate capacity from established, high-traffic routes to serve emerging airports. The validity of this model has been demonstrated using data from India's Regional Connectivity Scheme (RCS), which aims to promote air connectivity to unserved and underserved airports.

2 - Assigning airport ground-handling operations: an rVNS metaheuristic

Alexandre Dupaquis, Ronan Guivarch, Sandrine Mouysset, Daniel Ruiz, Vincent Charvillat, Frédéric Bouilhaguet

Airport ground-handling companies want to improve their operations all around the world want by automating current processes, and finding extra optimizations otherwise unreachable for human dispatchers. We aim to address the catering problem in the crossover between vehicle routing problems and scheduling problem, also known as the simultaneous supply & delivery problem. The MTCVRSPTW-MB (Multi-Trip Capacitated Vehicle Routing and Scheduling Problem with Time Windows and Meal Breaks) is extended to a heterogeneous fleet of trucks and drivers, with qualifications and different load patterns. We introduce a greedy heuristic to solve a relaxed version of the problem, as a baseline. Then, we implement a cooperative rVNS-based metaheuristic. We compare our algorithms on multiple real-life instances at San Francisco International Airport. Our computational study shows the effectiveness of each approach and brings out the strength of our metaheuristic. Our algorithms will help ground handlers specialized in catering operations, to speed up the decision-making process of assigning hundreds of tasks every day. In particular, we show the multiple extra benefits of the metaheuristic approach, including minimizing fuel consumption and the ability to re-assign tasks dynamically.

3 - Stochastic Dynamic Models for Reducing Air Traffic Delays at Heathrow

Rob Shone, Jamie Fairbrother

Imbalances between demand and capacity at the world's busiest airports cause air traffic delays, which can have serious financial and environmental consequences. To alleviate the burden on runway capacity, various types of interventions are possible. At the pre-tactical stage (up to a few hours before a day of operations), the schedule can be adjusted by imposing ground delays on flights in order to avoid "hotspots" of delay occurring at peak times. At the tactical stage (during the day of operations itself), sequencing of take-offs and landings can be optimised in order to minimise average time separations between runway movements.

This talk will discuss the progress of an EPSRC-funded project (EP/X039803/1) aimed at integrating pre-tactical and tactical interventions in order to reduce air traffic delays at Heathrow Airport. We formulate a stochastic dynamic optimisation problem in which the "system state" at any given time includes hundreds of variables evolving via continuous-time stochastic processes. Solution approaches via approximate dynamic programming are possible in theory, but very difficult to implement in practice. Instead we consider an approach based on the emerging field of "simheuristics", which involves continuously simulating possible trajectories of future random events and using a ranking and selection method to jointly optimise both runway sequencing and ground holding delay decisions.

4 - Airport Slot Allocation for Maximal Destination Coverage

Christian Truden, Margaretha Gansterer

Due to the escalating congestion at airports, there has been a growing interest in using optimization methods for airport slot allocation and flight scheduling. Level 2 and 3 airports nowadays have a substantial surplus of demand relative to airport capacity, which requires sophisticated slot allocation. This process is not only a computationally complex task but needs to satisfy the requirements of different players following individual objectives. The resulting allocation of slots and subsequent flight schedules significantly impacts the market power of airlines. From the passengers' perspective, the key consideration is connectivity, emphasizing the importance of viable connections between destinations. We propose an innovative slot allocation model that prioritizes destination coverage while considering limitations on market power for participating airlines. Based on an extensive computational study, we elaborate on how varying degrees of market power restrictions can positively or negatively influence connectivity.

1 - Density estimation for a moving crowd without a physical boundary

Pratik Mullick

The collective motion of social agents arising from their interactions has been the subject of intense scientific research. Understanding the collective dynamics of human crowds is crucial for improving pedestrian traffic flow, ensuring crowd safety, effective urban planning, and preventing crowd disasters. From the perspective of crowd management, it is crucial to understand the relationship between crowd density and velocity, known as the fundamental diagram (FD). This relationship helps to study the capacity of spaces where traffic moves, such as roads for vehicles and sidewalks for pedestrians. Constructing a realistic FD requires the utilization of an effective method for density estimation. While existing literature offers several methods, determining the 'best' method remains unresolved and may depend on the crowd situation. Most research has focused on situations where the moving crowd is constrained within a physical boundary, such as a corridor or sidewalk. However, there is no well-defined method of density estimation for groups in an unbounded space. I wish to present our recently developed voronoi-cell-based density estimation method that can estimate crowd density in a wide variety of situations, irrespective of the presence of spatial constraints. Our proposed method of pedestrian density estimation could facilitate the construction of FDs from the point of view of individual pedestrians, along their trajectories.

2 - Using Frequency Domain Analysis to Elucidate Travel Time Reliability Along Congested Freeway Corridors

Qixiu Cheng

Travel time reliability (TTR) is an essential measure of service for traffic performance management, especially for congested freeway corridors. This paper proposes a systematic analytical framework to analyze the predictable and unpredictable variations in route TTR in corridor networks. More specifically, the predictable variation in route TTR is estimated with a deterministic fluid-based polynomial arrival queue (PAQ) model, while the unpredictable variation in route TTR is analyzed through the residual induced by the PAQ estimation model. Based on the output of the PAQ estimation model, a frequency-domain approach is proposed to decompose the observed time-domain travel

time into underlying unobserved factors in different temporal resolutions. With the discrete-time Fourier transform method and the Butterworth low-pass filtering technique, it is capable of analytically uncovering different temporal scales of predictable variations in TTR, including the trend of day-to-day variations, the dynamics of within-day variations, as well as the stochasticity of within-period variations. Connecting with the unpredictable variations represented by the residual due to the PAQ approximation model, we can comprehensively elucidate TTR for congested freeway corridors. Case studies are conducted to show the effectiveness of the proposed frequency-domain approach in elucidating and measuring different contributing elements in TTR.

3 - Analytical Strategy for Optimizing Mixed Traffic Networks with Semi-Autonomous Vehicles

Hao Guan, Xiangdong Chen, Qiang Meng

Despite recent progress in semi-autonomous vehicle (semi-AV) development, achieving an optimal autonomous traffic system faces challenges due to the low penetration rate of semi-AVs and their need for human oversight. To improve traffic flow in such environments with human-driven vehicles (HVs) and semi-AVs, we advocate the use of dedicated lanes and develop an innovative framework to optimize the network performance by planning the mode choice of semi-AVs (either human-driven or auto-driven). Specifically, we introduce a three-dimensional Macroscopic Fundamental Diagram (3D-MFD) to characterize the complex flow dynamics in mixed traffic. Our analysis identifies that an optimal proportion of human-driven and auto-driven vehicles can significantly maximize network flow. Inspired by this key finding, we construct an optimization model to regulate semi-AVs' mode choice, aiming to optimize vehicle proportions within mixed traffic networks. Although solving the model presents challenges due to its nonlinearity and integer constraints, especially in large networks with numerous intersections, the unique structure of the proposed 3D-MFD enables us to derive an analytical solution. This solution significantly reduces the computational complexities of the optimization model, allowing the resulting control strategy to be implemented in real time and substantially improves network performance.

4 - Optimizing Urban Expressway Exit Ramp Lengths through Microscopic Traffic Flow Simulation: A Case Study Using PTV VISSIM

Yunzhu Lin, Yu Chang

This study presents a method using microscopic traffic flow simulation to assess urban expressway exit ramp layouts, addressing the problem of ramps too close to surface road intersections, leading to insufficient queuing space. Utilizing PTV VISSIM, a real-world case is analyzed over 65 minutes, including a 5-minute warm-up phase. The core simulation spans one hour, segmented into six 10-minute intervals. The research fine-tunes the Wiedemann 74 car-following model using comparative analysis of observed and simulated traffic volumes, adjusting parameters to match site conditions. Validation criteria require a percentage difference of under 10% and a GEH statistic below 5. Building on the validated base traffic model, which uses a 90-meter ramp length, the research extends the model to simulate scenarios with ramp lengths of 150, 200, 250, and 300 meters. Through linear regression analysis of the simulation data, relationships between traffic flow and density for these configurations are established separately. These findings are then mapped against the Highway Capacity Manual's service level density ranges to determine the optimal lengths for varying traffic flow conditions. The findings indicate a significant flow increase when extending the ramp from 150 to 200 meters, peaking at 250 meters. However, it also shows that a 200-meter ramp connection length optimizes queuing lengths, suggesting a balance between increased flow rate and minimized vehicle congestion.

Dynamic portfolio selection: stochastic optimization, filtering, and learning techniques

Stream: Modern Decision Making in Finance and Insurance

Invited session

Chair: Sebastien Lleo

1 - Reinforcement Learning Methods in Risk-Sensitive Investment Management

Wolfgang Runggaldier, Sebastien Lleo

We investigate the benefits of relating reinforcement learning (RL) with risk-sensitive control. Our starting point is the duality between free energy and relative entropy, see e.g. Dai Pra et al. (1996). It establishes an equivalence between risk-sensitive control and standard stochastic control problems with an entropy regularization term. This approach has two major advantages: i) it does not require a preliminary change of measure à la Kuroda and Nagai (2002); ii) it is naturally consistent with the use of a regularization/penalization term in the literature that connects reinforcement learning with stochastic control, e.g. Wang et al (2020). In this sense it also allows for a risk-sensitive interpretation of the entropy regularization in RL.

We furthermore show how this connects to the existing literature on risk-sensitive investment management (Kuroda and Nagai, 2002, Davis and Lleo, 2008, 2020, 2021), whereby cases with unknown parameters or with partial observation showcase the advantages of reinforcement learning.

2 - Robust Utility Maximization in Continuous Time: Filtering for Shaping the Uncertainty Sets

Jörn Sass

In financial markets simple portfolio strategies often outperform more sophisticated optimized ones. E.g., in a one-period setting the equal weight or 1/N-strategy often provides more stable results than mean-variance-optimal strategies. This is due to the estimation error for the mean and can be rigorously explained by showing that for increasing uncertainty on the means the equal weight strategy becomes optimal, which is due to its robustness. In earlier work, we extended this result to continuous-time strategies in a multivariate Black-Scholes type market. To this end we derived optimal trading strategies for maximizing expected utility of terminal wealth under CRRA utility when we have Knightian uncertainty on the drift, meaning that the only information is that the drift parameter lies in an uncertainty set. The investor takes this into account by considering the worst possible drift within this set. We showed that indeed a uniform strategy is asymptotically optimal when uncertainty increases. In this talk we focus on a financial market with a stochastic drift process and possibly uncertainty. We combine the worst-case approach with filtering techniques by defining an ellipsoidal uncertainty set based on the filters. We demonstrate that investors need to choose a robust strategy to profit from additional information.

3 - Expert Opinions and Power Utility Maximization in a Market with Partially Observable Gaussian Drift

Ralf Wunderlich

We consider optimal trading strategies in a financial market in which stock returns depend on a hidden Gaussian mean reverting drift process. Investors obtain information on that drift by observing stock returns. Moreover, expert opinions in the form of signals about the current state of the drift arriving at fixed and known dates are included in the analysis.

Drift estimates are based on Kalman filter techniques. They are used to transform a power utility maximization problem under partial information into an optimization problem under full information where the

state variable is the filter of the drift. The dynamic programming equation for this problem is studied and closed-form solutions for the value function and the optimal trading strategy of an investor are derived. They allow to quantify the monetary value of information delivered by the expert opinions.

We also study diffusion approximations of the filter processes for high-frequency discrete-time experts. They allow to simplify the problem and to derive more explicit solutions. Finally, we illustrate our theoretical findings by results of numerical experiments.

The talk is based on joint work with A. Gabih, H. Kondakji, J. Sass and D. Westphal.

4 - Portfolio optimization based on multiperiod continuous stochastic dominance principles

Giorgio Consigli

We consider a multi-stage generalization of the interval-based stochastic dominance (ISD) principles introduced by Liu et al. (2021). The ISD criterion was motivated specifically in a financial context to allow for contiguous integer SD orders on different portions of a portfolio return distribution against a benchmark distribution. A continuous spanning of SD conditions between first, second and third order stochastic dominance principles was introduced relying on a reference point. Here by extending the partial order to random data processes, we apply ISD conditions to a multi-period portfolio selection problem and verify the modeling and computational implications of such generalization. Several theoretical and methodological issues arise in this case that motivate this contribution. The problem is formulated in scenario form as a multistage stochastic recourse program and we study two possible generalization of ISD principles in which we either enforce ISD constraints on each stage, independently from the scenario tree process evolution, or we do so conditionally along the scenario tree. We present a comprehensive set of computational results to show that, depending on the benchmark investment policy and the adopted ISD formulation, stochastic dominance conditions of first or second order can be enforced dynamically over a range of possible values of the reference point and their solution carries a specific rationale.

Column Generation for Vehicle Routing

Stream: VeRoLog - Vehicle Routing and Logistics

Invited session

Chair: Jens Lysgaard

1 - A Column Generation Approach for the Routing of Electricity Technicians

Elise Bangerter, David Schindl, Meritxell Pacheco Paneque

The maintenance of an electricity distribution network involves numerous daily technical interventions. In this problem, we are given a set of interventions each with associated time windows, location, necessary skills and duration, as well as a set of teams of technicians with associated set of skills. We need to find feasible routes on the interventions for each team, considering the time windows and skills, and ensure that each team returns to its departure depot before the end of the day. The primary objective is to maximize the total duration of completed interventions and as a secondary objective, we aim to minimize the overall routing cost. This problem can be formulated as a capacitated vehicle routing problem with time windows. Due to the large number of teams and interventions, this results in a large-scale optimization problem, and its operational nature limits the time available for exact solving. Here, we propose a column generation approach where one subproblem per vehicle has to be solved and each potential route of a vehicle is considered as a new column in the master problem. To generate these routes, we rely on dynamic programming. Real-world instances from EDF (Electricité de France) of historical technicians'

interventions will be used to evaluate the effectiveness of the proposed methods.

2 - Mobile Production Vehicle Routing Problem

Min Wen, Stefan Ropke, Yu Wang

In this presentation, we will talk about the Mobile Production Vehicle Routing Problem, a new variant of the Vehicle Routing Problem. The objective of this problem is to determine a synchronized production and delivery schedule to minimize travel and delay costs. Previous work shows that CPLEX is unable to provide optimal solutions for most instances with more than 15 customers. This work aims to develop an exact algorithm to find optimal solutions for larger instances. We develop a branch-and-price algorithm for solving the problem. To accelerate the column generation procedure, an efficient dominance test and three heuristic pricing algorithms are developed to quickly find the columns with negative reduced costs for the pricing problem. Computational results on benchmark instances will be presented.

3 - On the Separation of Rank-1 Cuts in the VRPSolver Framework

Eduardo Queiroga, Teobaldo Bulhões, Anand Subramanian, Eduardo Uchoa

As one of the most extensively studied problems in operations research, the Vehicle Routing Problem (VRP) attracts considerable academic and practical interest. The state-of-the-art exact approaches for VRPs rely on the integration of cut and column generation within Branch-Cut-and-Price (BCP) algorithms. A critical component of modern BCP algorithms is the separation of non-robust cuts, such as rank-1 cuts with limited memory, which are considered strong but affect the structure of the pricing subproblem. In this research, we investigate algorithms for separating rank-1 cuts aimed at being both effective and efficient. The study involved implementing these algorithms within the VRPSolver BCP framework and comparing its performance against the existing local search-based separation method. Preliminary results of this study for the classic Capacitated Vehicle Routing Problem (CVRP) will be presented.

4 - A Set Partitioning Model for MinMax Vehicle Routing

Jens Lysgaard, Sune Lauth Gadegaard

This paper proposes a new approach to modeling of vehicle routing problems with a MinMax objective. At the core of the approach, a Set Partitioning model is formulated and used for minimizing infeasibility of the considered vehicle routing problem for a given upper bound on the objective value. Generally, the optimal value of the MinMax objective is obtained as the smallest upper bound for which the Set Partitioning model obtains a total infeasibility of zero. Computational experience shows very promising results.

asymptotic bias. This extends findings in the literature for assortment planning settings. Forward-looking consumers, anticipating and accounting for bias, prevent quality estimates from converging, hindering consumer learning. However, when a subset remains myopic, forward-looking consumers can disentangle bias, enabling convergence in quality estimates for both types. Illustrating implications for assortment planning, we show how incorporating consumer feedback influences revenue and consumer surplus. In online commerce, real-time consumer information allows personalized assortment decisions based on browsing history. Our findings illuminate the interplay between consumer learning, online reviews, and assortment planning, offering insights for navigating the e-commerce landscape.

2 - Using machine learning for constraint learning in multi-product pricing optimization

Luis Aburto, Vicente Ahumada

Multiproduct pricing optimization is a challenging process. Calibrating demand models based on transactional data tends to produce bias in cross-elasticity effects, mainly due to endogeneity issues, getting nonsensical or extreme solutions in the optimization process. We explore and compare different supervised and unsupervised methods to extract constraints from the data to formulate a robust feasible space for the pricing optimization procedure. These constraints or pricing rules uncover latent business rules where relationships between product prices happen. Also, they can identify price solutions correlated with good product category performance. We apply our methodology using the orange juice category dataset for different supermarket stores, obtaining robust improvements from 15% to 40% in expected category profit. Some of the methods used to extract pricing rules from data are association rules, SVM classifiers, robust optimization, and ellipsoidal kernels.

3 - Integrating Predictive and Prescriptive Analytics for Assortment Optimization - a Machine Learning-based Approach

Niloufar Sadeghi, Siamak Khayyati, Cornelia Schoen

Product line design is one of the key problems that firms need to solve. Therefore, they employ techniques to predict customer choice behaviour and optimize the performance of the product assortment they aim to offer. In most cases, the prediction problem and the optimization problem are defined as separate problems and solved in a sequential manner where first, the choice model is estimated and second, the assortment optimization problem is solved, using the choice model parameters as an input. Integrating estimation and optimization provides an opportunity for the empirical model to be more accurate where it matters - close to the optimal assortment. We develop a MILP formulation that is able to solve the two problems jointly. Using numerical experiments, we analyse under what conditions and to which extent the integrated approach is superior to the sequential approach.

4 - Estimating customer choice model and discrete dynamic pricing in the Online Bus Market

Akshitha Suryapeta, Suresh Jakhar

The Indian outstation tourism sector, valued at \$66 billion, sees substantial bus travel (50% of outstation journeys). The online bus market, currently at 5% (\$1.2 billion), is projected to reach 9.5% by FY25. One of the driving factors for this growth is the shift in customer behavior. Hence, our research focuses on studying customer behavior. The research objective is to evaluate the applicability of the choice model in predicting bus booking patterns and further solve discrete dynamic pricing problem. The primary hurdle is constructing an appropriate choice model, which involves various options that a customer contemplates while making their decision and identifying relevant attributes influencing their choices. To model choice behavior, the widely used Multinomial Logit model is adopted. The second challenge lies in the incomplete available data, with access only to booking records and no insight into browsing behaviors. To address this, we utilize an Expectation-Maximization (EM) method. In the first stage, we apply this estimation approach to simulated data, and then to the real bus booking data. The accuracy of our estimation is verified through calculations of asymptotic standard errors and goodness-of-fit tests, comparing the observed and expected booking counts predicted by our model.

Chair: [Erik Demeulemeester](#)

1 - A purely buffer-based approach to the proactive and reactive resource-constrained project scheduling problem

Yanfei Chen, Erik Demeulemeester, Jannik Matuschke

The proactive and reactive resource-constrained project scheduling problem (PR-RCPSP), introduced by Davari and Demeulemeester (2019b), addresses uncertainties in real-world projects in a novel manner. A PR-RCPSP solution is a proactive and reactive policy (PR-policy) that includes the baseline schedule and foresees potential transitions (reactions) to other schedules. In their subsequent work, Davari and Demeulemeester (2019a) categorize reactions into selection-based and buffer-based. While both classes are crucial, buffer-based reactions hold greater significance. Recognizing the theoretical importance and managerial value of the buffer-based reactions, we solve the PR-RCPSP using a purely buffer-based approach. To achieve this goal, we propose a method for generating a sufficient selection, along with proactive and reactive procedures, among other novel heuristics. We construct schedule pools from which we obtain optimal PR-policies. Experimental results show that our solutions outperform the best existing alternatives, particularly when reactions are less preferred, all while significantly reducing computational time. Remarkably, our purely buffer-based approach exhibits exceptional performance in instances featured by high resource factors or low resource strengths, situations where solving their deterministic counterparts presents greater challenges. Our results offer valuable managerial insights for navigating projects under uncertainty.

2 - Solving an integrated project and personnel scheduling problem using Dantzig-Wolfe decomposition

Brede Sørøy, Henrik Andersson, Anders N. Gullhav

We are considering a scheduling problem which consists of both scheduling activities in one or more projects, and the allocation of personnel and transportable equipment demanded to complete the activities. The activities are multi-modal and discretely preemptive, and there are precedence constraints that need to be respected.

Due to the challenges of scalability and efficiency when scheduling using direct mixed-integer programming (MIP) formulation and a MIP solver, we investigate the benefits of decomposing the integrated problem using a Dantzig-Wolfe reformulation. This method decomposes the problem into a master problem and one or several subproblems to find improving solutions.

The subproblem involves scheduling the activities of individual projects, and its solution is fed to the master problem as a new column. The master problem uses the project-schedule columns generated by the subproblems to find the best project-schedules to use so that personnel and equipment are allocated the most cost-efficiently. By decomposing the problem into project-specific subproblems that are quick to solve, the efficiency of the overall solution method is significantly increased. Our approach demonstrates promising performance in terms of computational time and solution quality when compared to solving the MIP formulation directly using a MIP solver.

3 - Solving the Stochastic Resource-Constrained Project Scheduling Problem with Flexible Resource Profiles using Sample Average Approximation

Ann-Kathrin Mendl, Julia Rieck

In today's competitive environment with short product life cycles and high customer expectations, working in projects is a predominant form of work organization. As part of the planning process, individual activities of a project are scheduled according to an objective function (minimization of the project duration) and the available renewable resources (e.g., employees) are used efficiently to carry out the activities. The resource-constrained project scheduling problem (RCPSP), also known as the standard model for project scheduling problems, assumes a constant activity duration and a constant resource requirement. Uncertainties that lie in the future are ignored. This entails the risk that considerable disruptions may occur in the schedule and the generated solutions are too restrictive for many practical applications. In order to account for uncertainties, stochastic aspects and flexible resource profiles are integrated into our problem.

Based on a chance-constrained model formulation, a sample average approximation model for flexible and stochastic project scheduling problems is presented. Small and medium instances are solved in a performance analysis. Furthermore, a suitable serial schedule generation scheme is developed, which is also applicable for larger instances.

4 - The resource constrained project scheduling problem with stability constraints.

Maria Elena Bruni, Oncu Hazir

In this research, we study a variant of the project scheduling problem with resource constraints (RCPSP) under uncertainty. In reality, in fact, project parameters are subject to considerable uncertainty, which generally leads to numerous schedule disruptions. Most optimization approaches focus on the quality robustness and only evaluate the relevance of the solutions through the objective function value. However, it can be more important to optimize the solution robustness, concerning the structural similarities between the nominal solution and the disrupted solutions. This translates into the need of developing robust schedules that can absorb disruptions as smoothly as possible and, once the uncertainty is revealed, find an alternative solution which is as similar as possible to the nominal solution. Following this stream, in this talk, we present a two-stage stochastic programming formulation for the RCPSP where in the first stage, scheduling decisions are taken considering the information available on the project parameters. In the second stage, the schedule is completely re-optimized leading to a new set of starting times, induced precedence relations and resource flows. We will incorporate solution robustness through stability constraints added into the model.

Hub Location

Stream: Locational Analysis

Invited session

Chair: [Sibel A. Alumur](#)

1 - A hybrid Lagrangian relaxation and Benders decomposition algorithm to solve stochastic hub location problems with profit maximization

Dung Tran, Nader Azizi, Thomas Archibald

This research addresses the profit maximization and pricing in a capacitated single assignment hub location problem. We assume that the demand between pairs of nodes in the network is price-sensitive and it is subject to uncertainty. The problem is formulated as a two-stage stochastic programming model, and a hybrid algorithm combining Lagrangian relaxation and Benders decomposition is developed to

efficiently obtain optimal solutions. We also discuss some acceleration techniques to improve the performance of the proposed algorithm. Some numerical results and managerial insights are presented.

2 - Hub location problem with a mixed green fleet

Okan Dukkanci, Achim Koberstein, James Campbell

This talk will introduce a novel hub location problem with a mixed fleet of diesel-based conventional vehicles and alternative fuel vehicles including electric vehicles and unmanned aerial vehicles. Compared to diesel-based vehicles, the driving range of alternative fuel vehicles in terms of travel distance is more limited. In addition to the driving range, the proposed problem also captures the capacity limitations of these vehicles. The objective function of the problem minimizes the total cost including the fixed cost of locating hubs and the transportation cost of different vehicle types. The latter cost component consists of the recharging cost associated with energy (fuel) consumption depending on the traveled distance, the recharging fee costs depending on the number of visits to recharging stations, and also the waiting cost for drivers and vehicles due to the recharging time of vehicles. We develop a mixed-integer linear programming formulation with preprocessing rules. Different extensions of the problem including a multiple allocation version and solution methods will be discussed. The talk will present computational results over the CAB, TR, and the newly introduced German datasets to analyze the impact of a mixed fleet of range and capacity-limited vehicles on optimal hub location and allocation decisions.

3 - A stochastic hub network design and protection problem

Armin Lüer-Villagra, Gonzalo Mendez-Vogel, Vladimir Marianov, Pamela Alejandra Bustamante Faúndez

The design of resilient hub-and-spoke networks has been previously explored in the literature, but in most cases, both the attack and defense strategies are deterministic and known by both the attacker and the defender. We study the problem faced by a company that aims to design a hub-and-spoke network despite the existence of one or more potential threats to the network operation. The company is tasked with a complex decision-making process. It must strategically determine the locations of its hubs, meticulously design the resulting hub-and-spoke network, and judiciously select which infrastructure to protect, all while considering potential threats to the network operation. The company faces one or more attackers, whose actions could potentially degrade the network operation. Importantly, the company operates in an environment of uncertainty, as it does not possess knowledge of the actual attack strategy, but has prepared several attack scenarios. The company's primary objective is to minimize design and protection costs. In contrast, the attacker's objective is to maximize them. We expect that the resulting models will provide valuable insights on how to design resilient hub-and-spoke networks, together with tools to quantify the impact of using heuristic protection strategies.

4 - Strategic Expansion of Freight Transportation Hub Networks under Uncertainty

Sibel A. Alumur, Hao Li, Gita Taherkhani, Mike Hewitt

We focus on freight transportation carriers that transport shipments that are small relative to vehicle capacity and incur transportation costs that exhibit economies of scale. To achieve profitability, such carriers route shipments through a network of hubs. The locations of a carrier's hubs dictate the customer markets it can profitably serve. We consider a carrier that seeks to increase its profitability by growing its customer base. To do so, it seeks to expand its network into new regions by merging with carriers that already operate in those regions. We focus on how, and by how much, the network that results from such a merger should be redesigned to maximize profitability. To study this issue we present deterministic and stochastic profit-maximizing hub location models that capture the interaction between economies of scale and profitability. The models differ in whether and how they model the recognition of uncertainty in shipment sizes in the decision-making process. We perform a case study based on operations from a multi-regional less-than-truckload freight transportation carrier to derive insights into the profitability of different redesign strategies. We analyze the networks prescribed by solutions to these optimization models to

derive insights into how a network that results from a merger should be redesigned. We also study how uncertainty impacts the structure of the redesigned networks.

Chair: *Jintao You*

1 - Platform-based stable truck matching problem with trailer-swapping mode

Wenxiang Peng, Zhaojie Xue, Xiangsheng Chen, Yubin Liao

This study investigates the platform-based stable truck-matching problem with trailer-swapping mode (STMP-TSM). The TSM is a novel collaborative transportation approach in which trucks participate in trailer swapping, significantly decreasing the rate of empty trucks and reducing transportation costs. In the STMP-TSM, a platform delivers a trailer-swapping scheme that satisfies all participating trucks. Correspondingly, an integer linear programming model is developed to maximize the total truck utility of the STMP-TSM. A specific preference list based on a chain-data structure is meticulously constructed to obtain a stable matching scheme. The preference list enables more generalized truck matching. In addition, a series of acceleration strategies is proposed to expedite the generation of a preference list while effectively reducing its length. An iterative preference-list-trim heuristic algorithm is designed, which strategically trims chains in the preference list to solve the STMP-TSM efficiently. As a benchmark, an integer linear programming model is developed based on the preference list to solve the truck-matching problem using the TSM. Finally, a series of numerical experiments are conducted to evaluate the performance of the proposed algorithm, assess the practicality of the TSM, and analyze the influences of the key parameters.

2 - An exact algorithm for the multi-trip container drayage problem with truck platooning

Jintao You

Container Drayage Problem (CDP) refers to the optimization problem of routing and scheduling a set of container trucks around a container terminal. Conventionally, a driver is stuck to one container truck and allowed to perform multiple trips (multi-trip) to the terminal within their working time. The recent development of automation technologies enables semi-autonomous trucks to follow the leading human-driven truck as a platoon on the road; therefore, truck platooning can save human labor and reduce the fuel cost of following trucks through aerodynamic drag reduction. In this paper, we study a multi-trip container drayage problem with truck platooning (MT-CDP-TP), where multi-trip, truck platooning, and fuel cost reduction are simultaneously considered in a CDP. Despite the operational benefits brought by the MT-CDP-TP, the problem is challenging to solve due to its NP-hardness when formulated as a multi-trip pickup and delivery problem with load-dependent cost. We propose a Branch-and-Price-and-Cut (BPC) algorithm, with a route-based set partitioning model and tight linear relaxations, to yield the exact solutions. Valid inequalities are generated based on a graph structure, where each node represents a feasible route, and each arc stands for the conflict between two routes. Moreover, we design a tailored pulse propagation algorithm with novel pruning procedures based on the dual information from the master problem and valid inequalities to solve the pricing problem efficiently.

3 - The Network Design and Refueling Station Location Problem for Green Maritime Corridors and Emission Trading

Xiaohuan Lyu, Frederik Schulte

The maritime shipping industry, responsible for 3% of global greenhouse gas emissions, is facing increasing pressure to decarbonization and ultimately zero emission due to the escalating threat of climate change. This urgent need has inspired the conceptualization of green maritime corridors—a designated network of shipping routes, ports, and associated infrastructure designed to advocate for shipping practices with low or zero emissions. Initial empirical studies have underscored the potential of green maritime corridors in advancing decarbonization. However, the shipping network and the requisite refueling stations to support alternative-fuel ships within the network remain undeveloped. Additionally, establishing green maritime corridors requires collaborative efforts from multiple stakeholders, wherein shipping lines, port operators, and governments are pivotal contributors, jointly ensuring the safeguarding of their respective interests. We first define the corridor network design and refueling station location and propose an optimization model to maximize the overall benefits, with and without an emission trading system such as EU ETS. We further design a cooperative game for profit sharing among involved stakeholders such that they are incentivized to cooperate in establishing the corridors. In this way, we provide a first optimization approach for green maritime corridor design, guiding policymakers and industry players on the way to successful implementations.

4 - Port Supply Chain Network Design for Customs Operations

Luis Ascencio, Claudia Caballini, Rosa G. González-Ramírez, María D. Gracia, Julio Mar-Ortiz

Coordination of inland flows with the hinterland is a difficult task, and lack of it results in long truck queues at the gates and unsatisfactorily conditions for truck drivers. In addition, the lack of space at ports and the limited resources demand efficient container handling operations to provide the required service levels to the ships and external trucks for transferring cargo. One critical operation related to container (or cargo in general) handling has to do with customs checks and inspections. The massive flow of cargo that is being handled at ports provides an opportunity for organized crime infiltration. For this reason, Customs plays an important role in securing international trade operations and stopping the flow of illicit products. However, inspections are time-consuming and costly, and container delays at an inspection facility can cause supply chain disruptions. Hence, one critical task for Customs and Port Authorities is to define strategies and operational policies to perform this operation, in which logistics infrastructure plays a critical role. In this paper, we propose a supply chain network design framework to locate different Customs facilities where the required inspections will be performed, with the aim of having more fluid operations in the dispatching of import containers. We assume that rather than having each port terminal its own Customs facility, the authorities have decided to locate external facilities to reduce container delays.

Natural Resource Management and Commodity Markets

Stream: OR in Banking, Finance and Insurance: New Tools for Risk Management
Invited session

Chair: Isabel Figuerola-Ferretti

1 - EU ETS Market Expectations and Rational Bubbles

Christoph Wegener

Concerns about a price bubble within the European Union Emissions Trading System (EU ETS) emerged during the third trading period. We argue that bubble tests based on costs for switching from cheap, polluting to costly, clean energy sources is restricted to situations of market certainty. This limitation is unrealistic, considering the ongoing CO₂ reduction measures. Additionally, establishing fundamental value through switching costs lacks a singular approach, leading to inconclusive findings. We propose a robust approach to infer bubbles in the EU ETS. Empirical findings do not support the presence of a bubble in the third or fourth trading period.

2 - Water as a commodity in hydropower generation

Isabel Figuerola-Ferretti, Eduardo Schwartz

The increased impact of extreme weather events and draughts has prompted the rapid growth of the water market. This paper analyzes the optimal operation of a reservoir that generates electricity and manages the water by trading water rights. We extend the framework introduced in a recent paper by Figuerola Ferretti, Schwartz, and Segarra (2023) to include the water price process in a model that accounts for water inventory and the electricity price as two independent price processes. The model is implemented under the stochastic optimal control approach and calibrated using monthly data for a reservoir in the estate of California. The water price dynamics includes the dependence on the California Drought Severity Index. Results show that the underlying water and electricity price dynamics exhibit a high degree of uncertainty and seasonality. They also demonstrate that, under the calibrated model parameters on average for the parameters used, around 25% of the revenue generated by the reservoir arises from the revenue obtained from selling water rights. The water contribution to revenue generation would increase under enhanced severity of climate change.

3 - Risk Management for Aquaculture Businesses in the Presence of Multiple Risk Sources

Christian Oliver Ewald

We will provide an overview about current modeling and analysis relevant to the financial, biological and ESG related risks in the optimal management of aquaculture businesses with particular focus on the Norwegian salmon farming industry. These results are based on the following research papers:

Ewald, C.O. and Kamm, K. (2024) On the Impact of Biological Risk in Aquaculture Valuation and Decision Making. <https://doi.org/10.48550/arXiv.2402.08686>

Ewald, C.O. and Kamm, K. (2024) On the impact of feeding cost risk in aquaculture valuation and decision making. Accepted and Published Online Quantitative Finance

Ewald, C.O. and Zou, Y. (2021) Analytic formulas for futures and options for a linearquadratic jump diffusion model with seasonal stochastic volatility and convenience yield: do fish jump? *European Journal of Operational Research*, 294(12)

Ewald, C.O. and Ouyang, R. (2017) An analysis of the fish pool market in the context of seasonality and stochastic convenience yield. *Marine Resource Economics*, 32(4), pp.431-449.

Ewald, C.O. , Ouyang, R. and Siu, T. K. (2017) On the market consistent valuation of fish farms: using the real option approach and salmon futures. *American Journal of Agricultural Economics*, 99(1), pp. 207-224. as well as research that is currently in development.

4 - The Role of Investor Sentiment in Commodity Price Behavior: Clarifying Evidence Based On Time-Varying Causality Tests

Roderick McCrorie, Mario Lupoli

Time-varying causality tests robust to mild explosivity, bubbles and crashes are used to provide a new, evidence-based perspective on commodity financialization, where money flows associated with index investors are conjectured to predict changes in commodity futures prices. We show that Singleton's (2014, *Management Science*) finding that money flows helped predict changes in crude oil futures prices is almost entirely attributable to the atypical behaviour of oil prices around the Global Financial Crisis, an aspect we show a standard Granger causality test applied over the whole sample is unable to pick up. Our approach helps settle what in the literature was an important but controversial finding. More generally, we corroborate some of the recent

results by Gilbert (2018) suggesting there is some causality between index investment and non-ferrous metals and some agricultural commodities, albeit commodity-specific and in a milder form concentrated in the aftermath of the GFC. The robustness of the test herein offers some clarity to an academic literature that has been settling against the efficacy and wider applicability of Singleton's results but has not been persuasive enough to see the same views become pervasive among finance practitioners.

Routing Unmanned Aerial Vehicles 2

Stream: VeRoLog - Vehicle Routing and Logistics
Invited session

Chair: Maria José Pinto

1 - Vehicle Routing Problem With Drones, Private Fleet and Common Carrier

Shouvik Bhattacharyya, Shalabh Singh, Sonia Singh

This article aims to analyse two distinct facets of last-mile delivery, namely drones and common carriers. Urban delivery is witnessing a surge in popularity of drones due to their ability to outpace traffic and exhibit minimal carbon emissions. Nevertheless, there are situations where a logistic provider may need to subcontract certain clients to a third party, commonly referred to as a common carrier, due to many reasons, including a faster turnaround time or a desire to reduce carbon emissions. The private fleet consists of multiple trucks and drones, and they serve customers independently from the depot. The common carrier informs the logistic carrier beforehand of the estimated delivery time and carbon emissions for all clients. The problem attempts to investigate the relationship between the two objectives, 'makespan' and 'carbon emissions' of the whole network. A bi-objective Mixed Integer Linear Programming (MILP) formulation is proposed. An iterative algorithm is designed for small to medium-sized problems that can sequentially generate pareto-optimal solutions. In addition, the results of a large-scale problem will be evaluated using a heuristic based on neighbourhood local search. Performing a sensitivity analysis on the parameters of the common carrier yielded some intriguing insights for the managers.

2 - Multiple Traveling Salesperson Problem With Drones: General Variable Neighborhood Search Approach

Selin Özpeynirci, Baybars İbroşka, Ozgur Ozpeynirci

A key factor to consider in the development of new technologies in a number of fields is the use of unmanned aerial vehicles (UAV). This rapidly developing technology is used in military, communication, health, mapping, agriculture and transportation fields. The importance of cargo transportation has grown due to the growth of e-commerce. Currently, with advancing technology, and the effect of the pandemic, purchases are increasingly made over the internet. For cargo transporters, this situation leads to an increase in the number of destination points, in distances traveled, and in the delivery frequency, and a decrease in the package sizes. As a result, the planning of transportation has become increasingly complex. One solution is to make greater use of UAVs in this sector, and to reduce reliance on trucks through appropriate planning. This involves two aspects: the UAV delivering to a point, while the cargo truck delivers to a separate point. In this study, we consider a multiple traveling salesperson problem simultaneously using multiple trucks and UAVs for package delivery. We develop a general variable neighborhood search algorithm, and compare the results with the existing studies in the literature. Computational experiments show that our approach is able to find highly satisfactory solutions in reasonable time, and outperforms the existing methods in terms of best solution, average solution and solution time in majority of the instances.

3 - Drone-Assisted Delivery Optimization: Balancing Time and Cost With Multiple Truck Routes for Efficient Service

Shalabh Singh, Sonia Singh

Conventional last-mile delivery logistical systems remain overburdened despite large-scale optimization. This paper explores the usage of drones to complement road-based last-mile delivery systems to ensure more time-cost efficiency. The work also extends the truck shipment routes to the case of real-time multiple routes. A bi-objective mixed integer linear program is introduced, accompanied by an exact solution methodology utilizing multi-choice conic goal programming. This approach efficiently solves smaller-sized problems. For larger instances, a three-step iterative heuristics is proposed. Exhaustive computational analysis and an illustrative case suggest that substantial savings in both time and cost can be achieved compared to traditional frameworks.

4 - An Air Route Planning Under Radioactive Plume Scenarios With Temporal Evolution

Maria José Pinto, João Camilo da Silva, Claudio A. Federico, Tássio Côrtes Cavalcante, Ana Cláudia Iwazaki, Monica Maria De Marchi

This work aims to support the decision-making process in the scope of Chemical, Biological, Radiological and Nuclear (CBRN) Defense, looking for the minimum radiation accumulated dose along the route for an aerial vehicle involved in rescue or transportation missions on situations of exposure to ionizing radiation by overflight within radioactive or nuclear plumes. A previous methodology was proposed to address the level of the radiation dose, the autonomy of the vehicle and the obstacles, when the vehicle is flying at low altitude or in urban areas where buildings or mountains are obstacles to the navigation. In this work, this methodology is improved by also taking the temporal evolution of the radiation dose into account, since the radiation dose may be different at the same location, depending on the specific moment it was measured due to the plume evolution. The proposed methodology will be presented and applied to illustrative instances.

1 - Empirically driven operations research for improving retail operations

Pedro Amorim

Retail is often the last supply chain node a product/service 'visits' before reaching the end customer. As a result, customers' behavior towards different incentives is paramount to managing retail operations, which combine elements of customer relationship management, supply chain and inventory planning, product distribution and logistics, pricing, and store management. Consequently, we must acknowledge that it may be hard to adhere to the common assumptions of operations research in this context – that all relevant variables and constraints can be identified and accounted for to achieve the ideal outcome. In this talk, we'll give a framework and examples for conducting empirically driven operations research to improve retail operations. The "empirically driven" approach has two main components: find an empirical justification of model assumptions and parameters and perform an empirical assessment of model results and insights.

1 - Rethinking Municipal Flood Mitigation: A Real-World Application of Operations Research Methods for Improving Climate Resilience

Jan Boeckmann, Clemens Thielen

Adapting to the consequences of climate change is undeniably one of the paramount challenges of our time. Among these consequences, intense heavy rain events pose a significant threat by endangering human lives and causing severe damage to infrastructure through flash floods. Recent events such as the heavy rainfall and flooding in Western Europe in 2021, Pakistan 2022, and Libya 2023, have once more corroborated the enormous potential for damage and underscore the importance of developing high-quality mitigation concepts in order to reduce the impact of these events on communities and their infrastructure. Such mitigation concepts, however, are typically elaborated solely based on simulations resulting in a time-consuming trial-and-error approach that provides no quality guarantee for the obtained solutions.

In this talk, an approach that combines mixed-integer programming and a combinatorial graph algorithm for the automatic computation of high-quality flood mitigation concepts consisting of retention basins, embankments, and ditches is presented. This, to the best of our knowledge, is the first automated decision support approach for this critical application that scales well enough to be applied to realistic scenarios. Apart from the developed optimization algorithms, the talk also presents a comprehensive web-application that has been designed to make the algorithms available to a broad variety of users beyond

the OR community. The work has been conducted within the project "Incentive Systems for Municipal Flood Mitigation" in an interdisciplinary team consisting of two academic research groups, an engineering office, two municipalities, and a municipal water association. By now, the resulting software has been used in practice by over 30 institutions from all over Germany reaching from local authorities over engineering offices to academic research groups. The empowerment of users with limited technical knowledge to design high-quality precautionary measures for pluvial flash floods sets the developed software apart from state-of-the-art approaches and marks a significant innovation showcasing the OR community's contribution to societally vital topics.

2 - The potential of renewable electricity in isolated grids: The case of Israel in 2050.

Ohad Eisenhandler, Gur Mittleman, Moshe Tshuva, Ronen Eran, Lev Zhivin, Yossi Luzon

The global urgency to mitigate climate change and reduce greenhouse gas emissions has intensified efforts to transition towards renewable energy sources. Isolated electrical grids, characterized by their detachment from larger networked systems, present unique challenges in this transition. This study, focusing on Israel's grid as a model for the year 2050, aims to address these challenges by employing a holistic approach that integrates advanced modeling techniques to assess the potential of renewable energy integration effectively. Employing a comprehensive methodology, this research incorporates a detailed Performance Model (PM) and an Energy Management System (EMS) model. The PM evaluates the hourly electrical output from diverse renewable sources, including solar (photovoltaics and agrivoltaics), on-shore and offshore wind, sea waves, and organic waste, taking into account Israel's specific geographic and climatic conditions. The EMS model then optimizes the alignment between this renewable energy supply, the anticipated demand, and necessary storage solutions. This approach includes extensive data collection on renewable energy potentials, area mapping for solar installations, and evaluations of wind and sea wave energy potentials based on geographical and meteorological data. The innovative aspect of considering organic waste adds an additional layer of resource diversification. The findings reveal a significant potential for Israel to increase its renewable energy share to between 80.1% and 99.5% by the year 2050, contingent upon the implementation scenario. Achieving such a high level of renewable integration hinges on developing substantial energy storage capacities. This research identifies a feasible combination of the Vehicle to Grid (V2G) concept, stationary batteries, and pumped hydroelectric plants as viable solutions for meeting the projected total electric demand of 183.3 TWh in 2050, with renewable resources providing an installed capacity of 180.6 GW. A key outcome of the study is the emphasis on agrivoltaics and the V2G concept as instrumental in enhancing the grid's renewable capacity. These innovations not only conserve land resources but also offer the requisite storage to manage the inherent variability of renewable energy sources. Moreover, the study underscores the importance of adopting a comprehensive energy management approach capable of accommodating the dynamic nature of renewable energy production and consumption. This research contributes to the broader discourse on renewable energy potentials in isolated grids, providing critical insights for policymakers, energy planners, and researchers. It underscores the feasibility and necessity of employing advanced modeling techniques to evaluate and optimize the integration of renewable energy sources, highlighting the need for significant storage capacities and innovative solutions like agrivoltaics and V2G. The implications of this study for energy policy and planning are profound, especially for regions with isolated grids similar to Israel. It encourages policymakers and energy planners to consider the methodologies and findings presented to make informed decisions regarding renewable energy investments and infrastructure development. Furthermore, the research highlights the pivotal role of innovation in energy storage and management technologies in maximizing the potential of renewable energy sources. In conclusion, the integration of renewable energy into isolated grids, exemplified by the case study of Israel in 2050, is both a viable and essential strategy for moving towards a sustainable energy future. This study lays the groundwork for future research to explore emerging technologies and storage solutions, ensuring that renewable energy can adequately meet growing demands while addressing environmental concerns.

3 - Formulation of Strategy Towards the ARCTIC in terms of Search and Rescue - Needs, Innovations, and AI/OR based solutions

Ashraf Labib, Dylan Jones

This seminar presents a usage of operational research methodologies during the ARCSAR (arcsar.eu) and AI-ARC EU-H2020 projects for enhancing safety and avoiding environmental damage in the Arctic and North Atlantic (ANA) maritime domain. The ARCSAR and AI-ARC (ai-arc.eu) projects arose due to concerns regarding the effects of increased maritime activity in the multi-national ANA region, caused by the melting ice due to climate change. The authors principal focus in the ARCSAR project has been working with search and rescue (SAR) and marine environmental response (MER) practitioners and other ANA stakeholders to classify and prioritise innovation needs. The overall aim is to lower the likelihood and social, environmental and economic consequences of large-scale incidents in ANA waters such as (i) a cruise ship sinking, (ii) a significant oil spill or (iii) a nuclear leakage. The AI-ARC project focused on developing and demonstrating an AI-based virtual control room that can improve decisions related to situational awareness, and assessment of risks against maritime incidents such as grounding, collision, oil spill, etc.

The seminar will first describe the holistic operational research process undertaken. This first involved a hierarchical classification of current and future ANA innovation needs, based at the highest level around the international maritime organisation (IMO)'s polar code. To achieve this, a series of workshops, questionnaires and interviews and literature review were used. These drew responses from 131 ANA stakeholders, including SAR and MER practitioners, environmentalists, NGO and charity representatives, indigenous peoples group representatives, industrialists and academics. This resulted in a hierarchical network of 20 need and 75 sub-need categories. A quantitative methodology using a combined PICK chart and Multi-Criteria Decision Making was then used to develop a priority set of 17 sub-needs. The PICK chart classified the needs according to importance and difficulty whilst a novel balanced knapsack goal programming model was developed to choose a high importance set of sub-needs, whilst considering the balance between long-term (more challenging) and shorter term (more implementable) innovation needs and across the six polar need categories.

The process of disseminating the methodology to ANA stakeholders and its usage to inform ARCSAR activities will be described. This involved a series of stakeholder workshops, where SWOT analyses around a set of the priority list innovations were undertaken. The priority needs were also used to inform significant activities, including a LiveEX ship evacuation exercise in Svalbard Norway. With respect to AI-ARC, the development of the risk index using AI based FL rule-based system and MCDM techniques to analyse data related to real-time AIS (ship conditions and position) combined with weather and human judgements will also be presented.

Finally, some highlights of the policy and practice impacts of the development of innovations to tackle the identified needs will be detailed. These include: [U+F0B7] The development of a set of training materials and procedures to use by ANA communities in the case of a nuclear incident [U+F0B7] An Arctic lessons learned arena for SAR and MER practitioners to share good practice [U+F0B7] Development of an AI-based virtual control room for safer ANA maritime navigation [U+F0B7] Enhanced training exercises and protocols for handling oil-on-ice in the case of an ANA oil spill [U+F0B7] Evidence given to, and cited by, a UK parliamentary enquiry on future Arctic policy [U+F0B7] Enhanced SAR operations in the Antarctic maritime region due to participation and knowledge transfer by Maritime New Zealand

Overall conclusions will then be drawn, including transferability of the developed methodology to other complex, multi-disciplinary situations where innovations to enhance safety and ensure wellbeing are needed.

(Deep) Reinforcement Learning for Combinatorial Optimization 2

Stream: Data Science Meets Optimization
Invited session

Chair: Kevin Tierney

Chair: Yingqian Zhang

1 - PolyNet: Learning Diverse Solution Strategies for Neural Combinatorial Optimization

André Hottung, Kevin Tierney

Reinforcement learning-based methods for constructing solutions to combinatorial optimization problems are rapidly approaching the performance of human-designed algorithms. To further narrow the gap, learning-based approaches must efficiently explore the solution space during the search process. Recent approaches artificially increase exploration by enforcing diverse solution generation through handcrafted rules, however, these rules can impair solution quality and are difficult to design for more complex problems. In this paper, we introduce PolyNet, an approach for improving exploration of the solution space by learning complementary solution strategies. In contrast to other works, PolyNet uses only a single-decoder and a training schema that does not enforce diverse solution generation through handcrafted rules. We evaluate PolyNet on four combinatorial optimization problems and observe that the implicit diversity mechanism allows PolyNet to find better solutions than approaches the explicitly enforce diverse solution generation.

2 - A regression model for selecting effective cuts in a Branch-and-Cut algorithm

Marcello Sammarra, Giovanni Giallombardo, Giovanna Miglionico

The performance of a Branch-and-Cut algorithm lies, among other things, in the ability of selecting a given number of available cuts to be added to the current LP relaxation, in order get to tight bounds. Clearly, adding many cuts the best bound improvement can be achieved, but, as a counterpart, also the time to solve the LP sensibly increases. Moreover, it is possible that only a fraction of the added cuts really contributes to the bound improvement, the remaining being not tight. This is to say the cut selection is a very challenging task. Modern ILP solvers, like CPLEX, GUROBI, XPRESS, MOSEK adopt greedy rules. Cuts are first ranked with a score function; then, cuts with the highest scores are added to the LP relaxation. In general, a cut score is a combination of well-established measures of cut quality, e.g. violation, parallelism, etc. Adopting as cut score the bound improvement, in this talk we show how a regression model can be learned to predict the cut scores for unseen ILP instances. Preliminary results and future research directions are discussed.

3 - Learning to Branch in Combinatorial Optimization with Graph Pointer Networks

Bo Jiang, Rui Wang, Gang Zhou

This paper proposes a novel graph pointer network (GPN) model to learn branching rules for branch-and-bound (B&B) algorithms in combinatorial optimization. B&B is a widely used exact method that can solve various NP-hard problems, such as set covering, facility location, and maximum independent set. However, B&B relies on manually designed heuristics to select the branching variables, which are often suboptimal and inefficient. The GPN model aims to automatically learn these heuristics from data, by imitating the expert strong branching rule. The GPN model consists of two components: a graph neural network that encodes the graph structure of the problem state, and a pointer mechanism that outputs the branching probabilities based on the global and historical features. The model is trained by minimizing the Kullback-Leibler divergence between the predicted and the expert distributions. Experiments on three benchmark problems show

that the GPN model outperforms both the classic and the state-of-the-art machine learning-based B&B methods in terms of solving speed and search tree size. The GPN model also demonstrates remarkable generalization abilities, adapting to unseen and larger instances. This paper presents an innovative approach to enhancing the performance of B&B algorithms using deep learning techniques.

4 - Learning to solve combinatorial optimization problems with a decision tree

Kevin Tierney

Deep reinforcement learning has made incredible strides in solving combinatorial optimization problems (COPs) and nearly outperforms the current state-of-the-art OR heuristics on several problems. However, a key drawback of deep neural network approaches is that they are not interpretable, that is, it is essentially impossible to understand how they actually solve optimization problems. To this end, I introduce a fully interpretable mechanism for generating interpretable models for solving COPs using a decision tree. The method harnesses a pairwise ranking mechanism to construct solutions, thus allowing it to learn to solve various instance sizes with a single model. To train the decision tree, I introduce an end-to-end learning technique to generate trees that are customized to specific datasets and show the effectiveness of this technique experimentally on several COPs.

Hybrid Approaches in Deep Learning and Machine Learning

Stream: Recent Advancements in AI
Invited session

Chair: Melisa Caliskan-Demir

1 - Auto-Pruned SOCP Clustering Problem

Duygu Üçüncü, Sureyya Ozogur-Akyuz

The selection of the best models in the ensemble has a pivotal role in the overall performance of ensemble learning algorithms due to the fact that redundant solutions in the ensemble library will decrease the overall prediction accuracy. Therefore, on account of eliminating such candidates, accuracy and diversity should be taken into consideration.

This study proposes a novel ensemble clustering method using a second-order conic optimization model that continuously and convexly solves integer programming for decision-making in various disciplines. The proposed model optimizes the balance between accuracy and diversity, resulting in the selection of the best candidates for prediction. The remarkable contribution of the study is the automatic sub-ensemble selection while optimizing for accuracy and diversity simultaneously. The model has been tested with real-world data and has achieved competitive prediction performance.

2 - Ensemble of YOLO Networks for Welding Detection

Melisa Caliskan-Demir, Alev Taskin

The YOLO series of neural networks is widely recognized within the domain of target detection due to its robust feature extraction capabilities, streamlined network architecture, and efficient detection speed, thus rendering it a cornerstone in contemporary research and practical applications. Ensemble learning, a technique that combines multiple learning algorithms, is employed in the literature to increase predictive accuracy. In this study, ensemble learning is judiciously employed with state-of-the-art object detection algorithms, including YOLOv5, YOLOv7, YOLOv8 and MASK R-CNN. The overarching objective is to refine welding detection outcomes by leveraging an original post-welding dataset comprising images captured from seed-throwing machinery utilized in agricultural contexts. The principal aim is to discern any potential faults within the welding processes applied to the

seeding legs of these instruments. The findings of this investigation underscore the superior efficacy of the proposed ensemble approach are compared with individual methodologies documented in extant literature. Although the YOLOv5 model manifests the highest individual performance metrics, the ensemble learning paradigm transcends these benchmarks, culminating in the most promising outcomes relative to the established performance criteria.

Cutting and Packing 4 - 3D irregular

Stream: Cutting and Packing (ESICUP)
Invited session

Chair: Jonas Tollenaere

1 - Optimized Packing Soft 3D Objects

Tetyana Romanova, Alexander Pankratov, Julia Bennell, Igor Litvinchev, Oksana Melashenko

Packing 3D soft objects in an optimized container is considered. The shapes of the objects can be varied in certain limits. However, the volumes of the objects remain constant. Free translation/rotation for objects is allowed. The soft objects must be arranged completely inside the container without overlapping. Corresponding nonlinear programming models are formulated for different shapes of objects using the phi-function technique. A solution strategy based on the multistart technique is proposed. It involves three main stages: search for feasible starting points; find a local-optimal solution for each starting point using a decomposition procedure; choose the best solution from those found at the previous stage. Computational experiments for packing soft polyhedra in a cuboidal container are provided. Packing soft objects has various applications in biology and mechanics, material science and logistics.

2 - 3D Irregular Cutting and Packing for the Nuclear Waste from Tokamak Fusion Reactor

Yifu Wei, Julia Bennell, Tatiana Romanova

The fusion reactor is widely regarded as the ideal future source of green energy. Nevertheless, the fusion reactor inevitably generates radioactive waste. The waste must be stored in waste disposal facilities for a significant length of time for legal and safety reasons. Subsequently, an optimised strategy of cutting and packing is critical to reduce overall costs which means a trade-off between cutting cost (the length of cutting trajectory) and the packing cost (the number of containers utilised).

My PhD research aims to tackle a 3D irregular cutting and packing problem: the primary shapes of the fusion reactor are treated independently, divided into distinct sub-problems. Each shape must be cut and subsequently packed into fixed containers. Regarding the containers, they are of a fixed, cylindrical or cubical design. The values of their cross-sectional area and height are predefined as parameters within the model. For each container, we also consider other parameters including the maximum permissible weight, maximum volume and the upper limits of radioactivity. The objective is to minimise the overall cost of cutting and packing.

In this presentation, I will provide a comprehensive definition of the problem, describe the way I will apply the phi-function techniques alongside a construction heuristic, and provide some preliminary results to illustrate how the approach works.

3 - A quaternion formulation of the volume maximization problem

Jonas Tollenaere, Tony Wauters

In volume maximization problems, the objective is to extract the largest three-dimensional item(s) with variable scaling from a larger container. To achieve this, values for the continuous translation and rotation variables should be determined so that the items can be maximally scaled up, without violating any containment or non-overlapping constraints. Applications of these problems appear in various real-world contexts, such as gem cutting and circuit manufacturing, where finding better solutions is typically highly valuable. While effective heuristic methods have previously been developed to tackle these problems, the attention to exact methods has been rather limited. One of the reasons for this is most likely the complexity involved with mathematically optimizing rotation in three-dimensional space. Angle-based rotation representations such as Euler angles lead to trigonometric expressions, which are challenging for exact solution methods. Therefore, quaternions are better suited for this purpose. Using quaternions, we can formulate the orientation of an object through quadratic expressions. This allows us to mathematically formulate volume maximization problems with convex containers as quadratically constrained programs, based on quaternions, that can be solved exactly. In this presentation, we will introduce volume maximization problems, give some insights into its applications and heuristic methods, and formulate the aforementioned quadratically constrained models.

4 - Optimization of automatic film dispensing of multi-layer films - The method of establishing material selection and scheduling

Gen-han Wu, Tzu-Yu Huang

In this study, we focus on the material selection and feeding schedule of four kinds of lamination films for the multi-layer automatic film dispensing problem in the polarizer industry process. The material selection is to select the appropriate size of each material film for lamination. The feeding schedule is to find the best sequence of automatic film dispensing for the selected materials. The scheduler in the plant has arranged the film dispensing manually, which has a great impact on the loss of materials. We develop a particle swarm optimization algorithm and two improved hybrid differential evolutionary algorithms to handle the material selection. The variable neighborhood search is designed to deal with the feeding schedule. The near-optimal solution can be found by iterative search. A series of experiments are designed to compare the search performance of these three swarm search algorithms. Three algorithms can achieve satisfactory results. In the future, these algorithms can be expected to develop the decision support system to the multi-layer film material selection and scheduling problem in the polarizer industry.

Invited session

Chair: Roman Slowinski

1 - The consistent electric-vehicle routing problem with backhauls and charging management

Pamela C. Nolz, Nabil Absi, Dominique Feillet, Clovis Seragiotto

We consider a consistent vehicle routing problem for the delivery of parcels with electric vehicles. Stemming from a real-world problem, we assume that vehicles can only be charged with electricity between their delivery tours in the morning and their pickup tours in the afternoon. For this purpose, a charging station with a limited amount of charging slots is available at the depot. We aim at generating a set of vehicle routes that are driver- and time-consistent and efficiently use limited charging resources, while optimizing the sum of vehicle fixed cost, vehicle/driver operating time, arrival time consistency and driver

consistency. We present a mathematical model to describe the problem in detail. For solving the real-world problem, a template-based Adaptive Large Neighborhood Search is developed, complemented with constraint programming for charging management and quadratic programming for delivery and pickup trip scheduling. Computational experiments for different settings and scenarios, based on data from an Austrian parcel delivery company, are presented and analysed.

2 - Deep Learning for Credit Scoring: Do or Don't - A retrospective look

Bart Baesens, María Óskarsdóttir, Wilfried Lemahieu, Björn Rafn Gunnarsson, Seppe vanden Broucke

New technologies such as deep learning should always be approached with scientific rigor. Using a unique and extensive collection of tabular data sets, we wanted to explore the potential of deep learning for credit scoring. We believe one of the key novelties of this paper is the robust empirical comparison framework we set up, using multiple datasets, evaluation metrics, confidence intervals, frequentist and Bayesian testing of significance. What we often encounter when reviewing papers, is that researchers either don't give baseline methods a fair chance or cherry pick them when comparing against their own newly proposed method(s). Furthermore, something rather basic but not unimportant relates to the title and message of the paper. We opted for a simple, easily Google-able title properly reflecting the research question which not only draws attention but also allowed readers to very easily grasp the key takeaways of our work. In this presentation, we elaborate more on this as well as how this paper helped shape our future research.

3 - Policy and facts about the European Journal of Operational Research (EJOR)

Roman Slowinski, Emanuele Borgonovo, José Fernando Oliveira, Steffen Rebennack, Ruud Teunter, Mike Yearworth

The session starts with two presentations done by authors of representative and highly cited papers published recently in EJOR. They represent two categories: Innovative Application of OR, and Theory & Methodology. Some further research developments and practical implications that followed these publications will be given by their authors. Then, the editors of EJOR will explain their editorial policy and will give some current characteristics of the journal. They will also describe their approach to the evaluation and selection of articles and will point out topics of OR that recently raised the highest interest. In the last part of the session, the editors will answer some general questions from the audience.

Uncertainties in the Energy Transition

Stream: Energy Markets

Invited session

Chair: Christoph Weber

Chair: Marco Sebastian Breder

1 - Distortions in energy related decision-making at households - An MCP approach incorporating system perspective

Marco Sebastian Breder

By using a variety of electrical appliances with smart control options, households might play a pivotal role in flexibility provision in the energy market. To exploit the flexibility potential in a most efficient manner from a system perspective, no distortionary impacts should affect operational and investment decisions. To date, most electricity tariffs do not reflect time-dependency in market prices. As a result, households' investment and operating decisions are based on distorted cost considerations. Scenarios become even more complex when EV owner install a second meter for wallboxes. In this case, two different electricity tariffs may be concluded. We elaborate on the distortionary impacts

of tariffs on households' investment and operational decisions under the current regulatory framework. Here we focus on investments in PV and battery systems under different tariff designs. Moreover, we exploit the case when a second meter with an additional tariff is in use for EV charging. We formulate the individual optimization problems corresponding to different types of households facing different electricity tariffs. Thereby households are differentiated according to their characteristics, i.e. (potential) Prosumer and EV ownership. A stylized wholesale market will allow to elaborate feedback effects from household decisions. The individual problems are combined into an overarching MCP problem.

2 - Cross-sectoral coordination in highly interconnected multi-operator energy systems: A distributed framework with autonomous agents

Aiko Schinke-Nendza, Christoph Weber

In response to Europe's climate objectives, this study investigates a novel distributed coordination framework for cross-sectoral integration in multi-operator energy systems, critical for achieving sustainability. Incorporating digitalization and decentralized resources, our method overcomes the challenge of efficiently coordinating highly interconnected systems while preserving data confidentiality and promoting renewable integration. We address nodal pricing efficiencies through a unique distributed algorithm that is based on autonomous agents—corresponding to market participants and network operators. This innovation ensures flexibility and efficiency, adhering to strict European regulations. Our approach not only handles the complexity of multi-energy carriers and the intricacies of highly interconnected power systems but also enables scalable, privacy-aware coordination avoiding major drawbacks of existing market designs. Based on a careful evaluation of decomposition techniques, we derive a distributed framework using the alternating direction method of multipliers (ADMM). Demonstrating the advances of this distributed algorithm, our research contributes to operational efficiency in multi-energy systems, enabling an enhanced integration of decentralized resources in a cross-sectoral energy system to meet Europe's ambitious climate targets.

3 - The effect of the variation of PV's effective capacity during the day-hours on the optimal capacity mix in a Cournot wholesale electricity market

Irena Milstein, Asher Tishler, C.k. Woo

This paper evaluates the effect of the variation of PV's effective capacity across the day-hours and the seasons of the year on the optimal capacity mix, generation levels and prices of a wholesale electricity market in which power producers use natural gas (NG) and photovoltaic (PV) technologies. The actual levels of PV's effective capacity during the day hours resemble the probability distribution function of a normal variable; it is very low in the morning, grows steadily until it reaches its maximal level during the midday hours, and then continuously declines during the afternoon hours. The shape of this distribution varies across the seasons of the year. Applied to Israel's stylized electricity market in 2030, we find that representation of PV's effective capacity by only two levels ("high" during midday hours and "low" during morning and afternoon hours) yields very similar optimal capacity mix to a representation in which PV's effective capacity changes during every hour of the day and over the four seasons of the year. We also show that using some NG during the day hours mitigates daytime price spikes and enhances consumer welfare. Finally, we show how technology improvements to the PV technology reduce the optimal PV capacity and electricity prices during the day hours.

4 - Evaluating the Economic Feasibility of Systematic Power Line Overloading in the German Electricity Transmission Grid Applying Chance-Constrained Programming

Hannes Hobbie, Lisa Lorenz, Miguel Anjos, Dominik Möst

Decarbonising the German energy system entails gradually substituting carbon-intensive power plants with renewable-based technologies. The need to integrate sizeable renewable quantities into the German electricity system affects the operation of future transmission grids.

Impacts also include an increasing congestion management requirement and associated costs. Managing grid congestion involves adjusting the market-based dispatch of single generators subject to grid constraints to find the least-cost system equilibrium. Grid constraints comprise rated thermal power flow capacities limiting electricity transmission. However, line capacities, to some extent, are subject to uncertainty. Increasing the line capacity is frequently practised by TSOs within certain boundary conditions, commonly called dynamic line rating. This gives operators greater flexibility, and indicates the importance of determining efficient capacity values. In this research, we propose to apply chance-constrained programming to investigate the economic feasibility of systematic power line overloading in the German transmission grid, utilising joint chance constraints to model probabilistic flow restrictions. Expected results will indicate its economic value and effects on congestion management cost depending on the probability level assumed. Outcomes also comprise line-specific information on realised single and simultaneous overload events across the time and lines providing TSOs with decision support.

Chair: Melanie Reuter-Oppermann

1 - Multi-modal routing and scheduling of drones, cargo bikes and vans in the presence of weather uncertainties for pathology collections in the Solent Area

Asrul Harun Ismail, Djamila Ouelhadj, Xiang Song, Andy Oakey, Antonio Martinez Sykora, Tom Cherrett

This research explores the impact of weather uncertainties on the ability of drones to improve pathology collections over the business-as-usual road-based logistics system in the Solent area of the UK. Weather uncertainties impact on the manoeuvrability and speed of drones, which can lead to delays and incidents. In this paper, we present a novel framework that combines a machine learning drone flight duration prediction model with a meta-heuristic Bees optimisation algorithm to solve the drone-cargo bike-van multimodal medical logistics problem in the presence of variable weather conditions.

Experiments have been conducted to evaluate how varying wind conditions affect drone schedule efficiency when used in combination with other transportation modes (cargo bikes and vans), and quantify the logistics system's overall economic and environmental impacts as a result. The case studies used concern the routine collection of pathology samples from doctors surgeries across the Southampton and Portsmouth area of the UK for delivery to pathology laboratories.

This study is part of the Solent Future Transport Zone project (FTZ) funded by the UK's Department for Transport and led by Solent Transport.

2 - A hybrid memetic-ANS optimization algorithm for the home health care and home care routing and rescheduling problem

Qiao Pan

This paper addresses a realistic home health care and home care problem which has become increasingly complex in the face of demographic aging and post-COVID-19 disruptions. The HHC&HC sector nowadays faces unique challenges in efficiently scheduling and routing caregivers to meet the rising demand. Traditional approaches often fall short in addressing the dynamic nature of care requests, especially in accommodating new, same-day service requests without compromising scheduled visits. To tackle these issues, We define the problem as an HHC&HC routing and rescheduling problem with rejection of new customers, focusing on rescheduling for a single HHC&HC caregiver in response to new customer requests within a single period. A

mixed integer linear programming model is developed to cater to two groups of customers: pre-scheduled existing customers and same-day service new customers. The model emphasized maintaining minimal disruptions to the original schedule for existing customers as a constraint, highlighting the balance between adhering to scheduled visits and accommodating new customers. A hybrid memetic-Adaptive Neighborhood Search optimization algorithm is proposed to tackle the model. This approach aims to minimize operational costs and opportunity costs while enhancing service quality and patient satisfaction. Through computational experiments, our proposed algorithm demonstrates notable performance, offering significant improvements in both efficiency and robustness.

3 - Allocation of Persons to Mental Health Homes by Knapsack-Based Routing

René Bekker, Rebekka Arntzen, Rob van der Mei

Persons with severe mental illness who cannot live independently can make use of long-term residential facilities. The matching process between client and facility is complex, as both restrictions and client preferences play a crucial role. For this, we introduce the Knapsack-Based Routing model, which combines and extends two lines of research: Skill-Based Routing models and queues with resources. We design an effective rolling-horizon heuristic by combining key ingredients from different elementary models. For small instances, we compare the performance with a Markov Decision Process formulation. For larger instances, we find that our heuristic outperforms the best-known policy for Skill-Based Routing with preferences for a benchmark instance (Chen et al, 2020). Finally, we apply our heuristic to a case study in Amsterdam and show how the current placement policy can be improved.

Behavioral Decision Analysis III

Stream: Behavioural OR
Invited session

Chair: *Gilberto Montibeller*

1 - The critical role of uncertainty communication in informed decision-making

Anna Cajochen, Nadja Contzen, Michael Siegrist, Judit Lienert

Our society is currently facing various sustainability challenges such as climate change, water pollution, and biodiversity loss. Decision-making problems aimed at solving these challenges are associated with considerable uncertainty. Uncertainty can arise from various sources such as measurement errors, difficulties to establish cause-effect relationships, disagreements between experts, or future unpredictability. Not only is the nature of uncertainty extensive, but other explanatory factors for effective uncertainty communication such as individual differences between recipients and the context of the situation must also be taken into account. Navigating the many factors essential to effective uncertainty communication makes this a challenging task. In our work, we examine the critical role of uncertainty communication from a decision analytical, economic, and psychological perspective. We address the definition, interpretation, and diverse communication formats for uncertainty, with a specific focus on enhancing understanding within multi-criteria decision analysis (MCDA) projects. It is crucial that stakeholders have an adequate understanding of uncertainty to identify their preferences and appropriate options. Therefore, our contribution is valuable for finding options to solve pressing sustainability problems and managing uncertainty in decision-making.

2 - Is lottery-based measurement of risk attitudes subject to a central tendency bias?

Rudolf Vetschera, Karl Akbari, Markus Eigruber

Lottery based questionnaires that let subjects choose among several lotteries with identical expected values are a popular way to measure risk attitudes. However, respondents have been shown to select a "middle" alternative too frequently, thus leading to an overestimation of the share of risk neutral individuals in a population. In this paper, we present the result of a comprehensive set of experiments testing the robustness of and different possible explanations for this phenomenon. In particular, we test for robustness in terms of (small) differences in expected values among lotteries, different levels of stakes involved in the lotteries, or whether respondents are incentivized. We also test for alternative explanations such as carelessness and overly fast responding, misunderstandings of the implications of answers or a general tendency to select an answer that is presented in the middle of a list. Our results indicate that carelessness and higher stakes increase the bias, while higher cognitive abilities and extreme levels of subjectively self-assessed risk attitudes decrease it. We find no significant effects of small differences in expected values or incentives.

3 - Optimization Models for Cumulative Prospect Theory under Incomplete Preference Information

Juuso Liesiö, Peng Xu

Prospect stochastic dominance conditions can be used to compare pairs of uncertain decision alternatives when the decision makers' choice behavior is characterized by cumulative prospect theory, but their preferences are not precisely specified. This paper extends the use of prospect stochastic dominance conditions to decision settings in which the use of pairwise comparisons is not possible due to the high or possibly infinite number of decision alternatives. In particular, we first establish equivalence results between these conditions and the existence of solutions to a specific system of linear inequalities. We then utilize these results to develop stochastic optimization models whose feasible solutions are guaranteed to dominate a specified benchmark distribution. These models can be used to identify if there exists a decision alternative within a set that is preferred to a given benchmark by all decision makers with an S-shaped value function and a pair of inverse S-shaped probability weighting functions. As such the models offer a flexible tool to conduct behavioral analyses in decision settings such as portfolio selection, procurement optimization or inventory management. We demonstrate the application of these models using real return data on industry portfolios.

4 - Selecting and packing bins - a human perspective

Johannes Kuchler, Leon Binder, Michael Scholz

The exponential growth of e-commerce in the past years has led to an increase in packages. Amazon, the biggest player in e-commerce, has packed and shipped approximately 7.7 billion packages in 2021. To handle that many packages, it is of utmost importance for e-commerce companies to optimize the packing process. The packing process consists of two decisions typically made by humans: the selection of the best-fitting bin for a given order and the packing of all articles of that order into the bin. There has been little research into how people make these decisions. We conducted two experiments to study the driving forces on the two decisions. In the first experiment, we varied the amount and heterogeneity of the available bins and the articles to be packed to examine the influence of these factors on the duration and quality of the bin selection process. We found, among other interesting insights, that the decision duration is, contrary to what is expected, not influenced by the heterogeneity of articles. In the second experiment, we varied the number and heterogeneity of articles to be packed into a predefined bin to examine the influence on the packing duration. Key findings of this experiment are that humans exclusively start by packing the largest item and that packing an additional article increases the packing time by 4.3 seconds on average. Our findings contribute to the understanding and optimizing the packing process.

Chair: Hugo Herrera

1 - Mission (Im)Possible: universities' focus on the agri-food sector

Chiara Colamartino, Pierluigi Toma

The agri-food sector requires evolutions capable of addressing the ever-present climate crises. Innovations in agri-food are increasingly supported by research theories and methods. Universities may represent the local drivers of rural development, providing training and research to orient small and territorial realities to innovation. Collaboration between agri-food and university can help to improve practices and safeguard the environment. First, this study explores the Strategic Plans of Italian universities, examining their objectives via text analysis techniques and clustering words from strategic plans. Second, the research compares the distribution of keyword clusters with the growth in revenues for agri-food companies, the actions conducted to implement the three Missions of universities, and the spread of agri-food startups and spin-offs on the territory. The Kernel Density Estimation (KDE) permits obtaining a non-parametric density estimator to explain multi-modal variables by better following the pattern of the histogram. These findings may emphasise universities' external relations on the territory to improve the innovation process and to boost partnerships with nearby agri-food firms. Besides methodological instruments and interpretations of intellectual capital for variable selection, the work may introduce novelty to the literature on the collaboration of the agri-food sector to local development.

2 - Valuing harvesting technologies rental cost using a simulation approach

Sergio Maturana, Elbio Avanzini, Carlos Monardes, Pablo Acevedo

Which harvesting technology to use is a crucial decision for farmers, particularly when dealing with perishable products. Renting machinery is customary for many farmers, with costs fluctuating based on the machines' features, yearly conditions, and the producer's willingness to pay. Negotiations on rental discounts often occur, especially when renewing machine rentals.

Employing simulation and decision rules, we assess the problem of choosing between different technologies that a wine grape farmer might use when harvesting. Besides the cost differences, the machines behave differently in rainy conditions. The occurrence of rain and its intensity is difficult to predict when the farmer must choose which machine to use. The farmer might also decide not to rent any equipment, so they won't be able to harvest for some time.

The farmer navigates harvesting decisions through a multidimensional utility function applied across numerous scenarios spanning several years, with rainfall intensity as the critical uncertainty. We performed numerical experiments using Monte Carlo simulation to evaluate the use of different technologies. We analyzed the results to determine how well the proposed approach can consider the operational complexity of harvesting using different types of machines and under uncertain weather conditions. This can help make a better decision when choosing which machine to use in the initial year and the switching costs in subsequent years.

3 - Bioeconomy transition, using hybrid simulation to assess challenges and opportunities for livestock farmers in Norway

Hugo Herrera

The bioeconomy is a crucial concept for addressing major environmental challenges. Transitioning towards a bioeconomy requires coordinated efforts from various stakeholders and has the potential to significantly transform value chains, particularly in the agriculture sector.

However, the pathway to this transition is complex and dynamic. This paper aims to shed light on this complexity by employing a hybrid simulation approach that integrates system dynamics and agent-based simulations. Our focus is to explore both the intended and unintended changes that a bioeconomy transition might bring to dairy livestock farmers in Norway. The contributions of this paper are twofold. First, it examines the advantages and drawbacks of using hybrid simulations to model farming systems. Second, it offers practical insights into the impact of introducing and promoting new biotechnologies in the industry. In particular, the simulation results highlight significant challenges regarding a bio-based economy for dairy farmers resulting on the potential exacerbation of the previous trend towards fewer, larger, and more intensive farms. Moreover the simulation results also indicate a potential geographical concentration of farms in small areas of Norway. The potential concentration of farms in very few hotspots for dairy farming is a consequence of the scales needed to justify investments in supportive infrastructure like bioreactors.

4 - Resilient Olive-Oil Supply Chain Network Design

Bilge Bilgen

This paper addresses the integrated planning problem encompassing olive harvest and production within the olive oil industry. The aim is to optimize a mathematical model that seamlessly integrates both olive harvest and olive oil production processes. The primary goal is to maximize overall profit by determining the quantities of olives harvested from various groves, olives procured from external farmers, olive oil produced, and managing by-products to mitigate the adverse impacts of olive oil production. The problem is formulated as a mixed integer linear programming model (MILP). Profit maximization comprises total sales revenue and total costs, covering harvesting, procurement, fixed and variable processing expenses. System constraints include harvest and production planning, capacity limitations, and processing restrictions. The proposed MILP model encompasses several distinctive aspects of the problem, such as olive ripeness, olive oil quality, farming methods (organic and conventional). Backup facility assignment and coverage distance resilience strategies are incorporated. The effectiveness of the developed model is validated through a numerical experiment based on a real-world case study, indicating that simultaneous consideration of harvesting and production processes significantly enhances the profitability of the olive oil supply chain.

Methodological Developments in Soft OR and PSMs

Stream: Soft OR and Problem Structuring Methods

Invited session

Chair: Chris Smith

Chair: Ashley Carreras

1 - A Structured Decision Making approach to Improve Population Health and Reduce Health Inequalities

Shraddha Ghatkar, Emma Comrie, Joao Duro, Ping Li, Corinna Elsenbroich, Visakan Kadiramanathan, Robin Purshouse

Multi-Criteria Decision Making (MCDM) and Multi-Criteria Decision Analysis (MCDA) are widely used with problem structuring methods to support thinking and decision-making in real-world applications. Within MCDM, Multi-Objective Optimization (MOO) is a commonly used method and yet, review of the literature highlights lack of studies employing a structured method to develop MOO problem formulation from a real-world application and to incorporate stakeholder involvement. Traditionally, research related to MOO focuses on development of solution algorithms, working with a pre-developed mathematical problem formulation. As part of an ongoing research consortium - SIPHER (Systems Science in Public Health and Health Economics

Research), we are working with policy partners to develop a Decision Support Tool (DST) that can be used by budget holders in identifying where to target policy action while considering multiple and potentially conflicting outcomes and performance metrics at the same time. We have employed a mixed-method approach in the DST which combines participatory systems mapping with subject-matter experts, developing an evaluation model for the potential policy options and co-working with policy partners to elicit MOO problem formulations. In this presentation, we give rationale for using this approach, our experience of using it along with policy partners, lessons learned and future directions for research.

2 - The philosophical, theoretical and methodological development of a PSM through Action Research: From the Specific to the Generic

Chris Smith

This paper considers the development of a Problem Structuring Method (PSM) WASAN over an action research programme and what we can learn about the applicability of PSMs to multiple contexts. The programme focusses on WASAN's developmental journey from a single use approach, only applicable to a limited context, to a PSM that has generic applicability, that is can be used across multiple problem contexts. The project tracks the changes made to WASAN through 11 Learning Loop cycles across two new problem contexts with five different researchers using the approach to collect and analyse data. The unit of analysis for the paper is the philosophical, theoretical and methodological development of WASAN, to achieve this the paper focuses on the learning from a second level analysis of the Action Research Programme concerned with what we can learn about PSMs more broadly. Here the focus is the different classes of elements within WASAN which are required for it to be generically applicable, that is applicable to a variety of problem contexts. Here the paper distinguishes between two classes of elements, those which required consistent replication regardless of context; termed methodological elements. Second, those which allow an approach to be applicable to the local context thereby bridging the gap between the problem context and methodology; we term these contextual elements.

3 - Indispensable and Identifiable activities and the link between group goals and individual goals following Causal Mapping Interventions.

Ashley Carreras, Welf Weiger

Within the Problem Structuring Methods literature, it is widely held that undertaking a Causal Mapping session on the ultimate goals of a set or prioritized actions contributes to a greater likelihood of achieving those goals. An alternative approach to understanding the nature of this link between group goals and individual actions undertaken in the pursuit of these group goals is offered by drawing upon the psychological concepts of "Indispensable" and "Identifiable" activities. These highlight the difference between self-serving and group-serving activities in a group environment. Participants of group assignments from an MBA program were surveyed during and after the production and submission of a group assignment, with some participating in collective agreement group activities before the commencement of the assignments.

4 - Listening to act: Using Rich Notes for problem structuring in small groups

Karthik Suresh

Practitioners using problem structuring methods (PSMs) help participants in groups make sense of a situation they consider to be problematic and find consensus positions that enable action to be taken to improve the situation. Many approaches encourage participants to co-create models by picking up pens or markers and getting involved. Less attention is paid to how participants or practitioners listen to different perspectives, integrate different points of view and document findings. Listening is more than a single ability and can be conceptualised in different ways such as listening as information processing, listening as comprehension, and listening as retention, among others. This paper introduces listening using Rich Notes, a novel approach to note taking and diagramming during meetings that uses a non-linear,

non-hierarchical, unconstrained and distributed layout that documents what participants say, recognises interdependencies and generates options for action. Rich Notes has been developed within an action research programme consisting of over 300 real-world participant interactions.

Modelling European market coupling

Stream: Energy Markets

Invited session

Chair: Marc Deissenroth-Uhrig

1 - Evaluating Offshore Electricity Market Design Considering Endogenous Infrastructure Investments: Zonal or Nodal?

Kenneth Bruninx

Policy makers are formulating offshore energy infrastructure plans, including wind turbines, electrolyzers, and HVDC transmission lines. An effective market design is crucial to guide cost-efficient investments and dispatch decisions. In this talk, we jointly discuss the impact of offshore market design choices on the investment in offshore electrolyzers and HVDC transmission capacity. We present a bilevel model that incorporates investments in offshore energy infrastructure, day-ahead market dispatch, and potential redispatch actions near real-time to ensure transmission constraints are respected. Our findings demonstrate that full nodal pricing, i.e., nodal pricing both onshore and offshore, outperforms the onshore zonal combined with offshore nodal pricing or offshore zonal layouts. While combining onshore zonal with offshore nodal pricing can be considered as a second-best option, it generally diminishes the profitability of offshore wind farms. However, if investment costs of offshore electrolyzers are relatively low, they can serve as catalysts to increase the revenues of the offshore wind farms. This work contributes to the understanding of market designs for highly interconnected offshore power systems, offering insights into the impact of congestion pricing methodologies on investment decisions.

2 - Assessing the Impact of Cross-Border effects on Day-Ahead Market Electricity Prices - a Meta-study

Jilles De Blauwe

Cross-border effects play a significant role in shaping spot market prices. Yet, a thorough meta-study synthesizing their influence and comparing across different European markets remains a gap in relevant literature. Further, a comparison of the relevant literature on the basis of the methodology followed in each study can prove useful. This meta-study will therefore investigate the relevant existing literature for papers that have established a relation between a cross-border effect and the spot market prices. A number of key cross-border effects of particular interest are first identified, before compiling a comprehensive list of relevant papers that include those effects. Subsequently, the study will rigorously compare the selected papers on a methodological basis. Here the study will classify the papers for modelling technique used, the time period on which influences are defined (short and long-term) and the market under study. These methodologies will then be discussed. Finally, the conclusions of different papers looking at a particular effect are compared, to assess whether the difference in results drawn in the papers might result from the modelling technique and the methodologies followed in that paper, or was rather due to some other factors. This meta-analysis will thus provide a valuable reference tool for future studies that seek insight into methods to analyze or forecast spot market prices while including cross-border effects.

3 - Methodology and results of characterization of strategic bidding strategies

Henrik Mantke

As part of the research project "Bidding strategies and their influence on electricity market prices in the EU single market (BETS)" a methodology for characterization of strategic bidding strategies was developed. One of the main targets of the project is the development of a strategic bidding agent for agent-based electricity market models. A special focus will be on the cross-border strategic bidding. An important step for the implementation of the agent is the definition of different strategies that the bidding agent should use, and that could be found in today's EU spot market. In this context, based on a profound literature research, a methodology for characterization strategic bidding was developed. A focus was set on aspects of the core bidding strategy, the field of application, such as the markets or the used solution and price methodology. Also, different boundary conditions considered in the literature, focus technologies or uncertainty about information for the bidders were considered in the characterization. With this methodology the relevance of different strategies could be analysed and relevant cross-border strategies could be specified, even if they have been analyzed only for individual market areas.

4 - Local Network Coordination - A Market Design for Trading Congestions

Paul Seifert, Steffen Bakker, Stian Backe

Getting new grid access permits is challenging for Norwegian grid customers to a shortage of transmission system capacity. Grid reinforcements require long lead times and are not expected to ease the situation soon. If capacity limits are reached, requests face rejections for grid access. Grid managers have to ensure capacity limitations are met all the time. Enough capacity is available for most of the time, but some critical hours see spikes in which load profiles layer to unfortunate spikes. The consequences are severe and hinder economic development. So far, there are no signals indicating the grid's status on which coordinated actions could be aligned. Upcoming congestion hours are not foreseeable, nor exist incentives to influence load profiles according to grid status. Alternatively, we advocate for congested customers to team up with entities with existing capacity rights and pool them in energy (capacity) communities. Steered by price signals from utility-cost equilibria, members coordinate their load profiles and assign capacity scarcity prices if a capacity violation occurs. We designed a two-stage combination of load flow optimal dispatch models with an equilibrium model to resolve the congestion. We demonstrate that this market design enables more customers to join the electricity grid through an efficient price-based trading mechanism, which adheres to grid restrictions, is incentive-compatible, and allows cost recovery.

Monday, 14:30-16:00 - Room: 18 (building: 116)

Healthcare services

Stream: OR in Health Services (ORAHS)

Invited session

Chair: Man Yu

1 - A Markov chain for the evaluation of inpatient flow in hospitals

Anders Reenberg Andersen

Many hospitals face the challenge of an increasing demand for admissions to their inpatient nursing wards. The possible solutions to this problem include relocating patients, merging nursing wards, and optimizing the balance of bed capacity between them. In any case, hospital planners need a model that describes the influence of the admission rate, length of stay, allocated capacity, and relocation policies on the occupancy of beds. This study proposes a model based on a continuous-time Markov chain. We reduce the model's computational

requirements by evaluating each ward separately and approximating the process governing patients arriving from the other wards. We base our approximation on interrupted Poisson processes, where the interruption times follow hyper-exponential distributions. By employing this approach, we are able to evaluate the occupancy of all inpatient nursing wards in a Danish hospital. Our numerical experiments indicate that this approach is insensitive to the length of stay distribution type and accurately reflects the occupancy of many wards in the hospital.

2 - Dynamic Contracts For Queuing Service Systems

Ji Chen, Man Yu, Laurens Debo

We analyze a service provider's optimal design of service contracts, which specify service priority and pricing for consumers (e.g., patients) of different types. The analysis incorporates both static and dynamic contracts and considers consumer heterogeneity following either discrete or continuous distributions. It demonstrates the profit advantage of dynamic contracts over static contracts and characterizes the conditions under which the advantage is most pronounced.

3 - Generalized or Specialized Hospitals: An Analytical Queuing Approach to Explore Clinical Service Configurations

Mohammad Aminjarahi, Navid Izady, Dimitris Paraskevopoulos

In multi-hospital networks (MHNs), a critical decision revolves around how to allocate clinical services across different hospitals with limited capacity. This decision typically falls between two extremes: a fully generalized configuration where all services are offered in every hospital, and a fully specialized configuration where each hospital exclusively provides one service. However, research and practical evidence indicate that neither fully specialized nor fully generalized configurations are optimal. In this paper, we present a mathematical model along with an exact analytical solution to explore the optimal service configuration within an MHN comprising two hospitals of equal fixed capacity and two services. Our model addresses uncertainty by incorporating queueing theory and economies of scale, crucial factors in service configuration problems. Through extensive numerical experiments, we demonstrate that, in most scenarios, a semi-specialized configuration emerges as optimal, maintaining one hospital as general and the other as specialized. Nonetheless, there are specific circumstances where alternative configurations, such as fully specialized or fully generalized, may prove optimal.

4 - Admission Pricing In Public Emergency Departments: Theory And Evidences From A Natural Experiment

Man Yu, Ji Chen, Tian Li

We study the pricing decisions of a medical service provider who operates both an emergency department and a non-emergency department with different priority schemes and admission fees. Each patient independently makes her attendance decision according to the urgency level of her medical condition, the admission fees, and expected waiting time at the two departments. We characterize patients' equilibrium attendances to the two departments. Effects of adjusting the admission fees on patient attendances are examined both in an analytical model and with empirical data from public hospitals in Hong Kong.

Stream: OR Education

Invited session

Chair: Martina Gregori

1 - Application of MARS Method to analyze students' choices of OR courses

Jinal Parikh, Gerhard-Wilhelm Weber

Given that operations research provides its learners with an exposure to an array of problem-solving and decision-making analytical techniques that can be applied to all areas and domains for solving complex decision-making problems, its importance in higher education cannot be understated. The purpose of this paper is to first investigate the factors that influence students' choices of OR courses at Universities of Higher Education in India. Next, we apply MARS method to predict students' choices of these courses.

2 - Performance assessment of higher education institutions in the philippines: a dea approach

Milagros Baldemor

This study determined the performance assessment of the six (6) State Colleges and Universities of Northwestern Philippines vis-à-vis their performance along the following indicators: Graduation Outcomes, Research, Outreach and Inclusivity, and Teaching and Learning Outcomes for five (5) academic years 2016-2020. It utilized the Mamquist DEA Approach, a non-parametric measure. Furthermore, it determined the peer groups and weights of the DMUs (Decision Making Units - the different Colleges and Universities), the virtual inputs/outputs or potential improvements of the colleges/universities to be in the efficient frontier, the input and output slacks (input excesses and output shortfalls) needed in the different indicators and the best practices to be considered by the inefficient and weak efficient DMUs. The "best practice" in the frontier is the basis to calculate the adjustments necessary for the DMUs. Different indicators showed varied performance levels in the different academic years but there are best practices from the "efficient" DMUs which could be adapted by the "weak efficient" and "inefficient" ones.

3 - Optimizing food donation delivery for nonprofit company Logica&Co

Martina Gregori, Anna Livia Croella

We present a case exercise teaching students how to apply mathematical programming to a real-life context. The case deals with food donation supply chain management. Using a project-based approach, the case proposes a realistic scenario simulating the consultancy interaction with the (fictional) nonprofit company. The Logica&Co acts as a two-sided platform connecting supply and demand. The objective is to define an effective strategy for collecting and delivering food donations from local businesses to soup kitchens over a semester-long timeframe. The problem exhibits non-linear characteristics; however, it is designed with adjustable difficulty levels. An interactive offline tool, the SoS simulator, can be furnished to students for performance assessment. The tool is publicly available for download and can be customized by the instructors. The case was proposed as a competitive group challenge to students of the Bachelor's or Master's program in Management Engineering at Sapienza University of Rome. Students appreciated both the teaching methodology and the teamwork aspects; they highlighted the utility of the SoS simulator tool.

Ali Hajjar, Oguzhan Alagoz

Existing clinical practice guidelines tend to overlook the unique requirements of patients with multiple chronic conditions (MCC) by primarily focusing on the management of individual diseases. This inadequately personalized approach leads to adverse events and places a financial strain on the healthcare system, particularly in countries with large or growing populations. To address this issue, our study utilizes a stochastic modeling approach to optimize disease screening decisions while considering financial and resource limitations from a broader societal perspective. Our findings indicate that women with pre-diabetes should undergo less frequent screening compared to those without diabetes. Moreover, our numerical results demonstrate the robustness of the optimal breast cancer screening policy in the face of relative changes in mammography screening costs.

2 - Optimal Usage of Packed Red Blood Cells in Preterm Neonates Requiring Frequent Small-Volume Transfusions

Malavika Krishnakumar, Merin Mathew, Anjali Ajith, Sruthi Suresh, Perraju Bendapudi, Linda John, Dhanya A, Veena Shenoy, Georg Gutjahr

Preterm neonates with low birth weight often require frequent small-volume blood transfusions. Instead of addressing each transfusion event individually, reserving blood bags in advance may prove to be economical and minimize donor exposure. However, it might introduce storage challenges and could lead to the wastage of blood. An optimal strategy for reserving blood bags depends on neonatal clinical characteristics and available blood reserves in the transfusion service.

To model this decision problem under uncertainty, we assume that the known and unknown random variables are structured as a Bayesian network and will use a partially observed Markov decision process. At each day, the state of the process is described by the blood inventory and the neonatal clinical characteristics. Neonatal gestational age, weight, and medical conditions are observed variables. In contrast, the length of stay and the total amount of required blood are unknown at the time of decision-making.

The proposed model can be expressed as a dynamic Bayesian network model in which the decision variables can be optimized by dynamic programming. We explore the sizes of the problem instances that can be solved in this exact way and also propose an efficient approximate dynamic programming method for large instances. We illustrate the methods with one year of data from a neonatal ICU in South India where financial and blood-availability constraints play a crucial role in finding optimal strategies.

3 - The "Netflix Model": A New Payment Model for Asymptomatic Disease Management

Huaiyang Zhong

In the U.S., over 3 million are estimated to have hepatitis C, with many cases undiagnosed. Early detection of hepatitis C is crucial but hindered by high screening and treatment costs. The paper discusses how Netflix-style contracts could incentivize increased screenings and treatment by offering fixed payments for unlimited drugs

4 - Selection of Glucose Monitoring Devices Using the Co-CoSo Method: An Innovative Approach to Diabetes Management

Antonio Sergio da Silva, Marcos Santos, Carlos Francisco Simoes Gomes

This study aims to implement the Combined Compromise Solution (CoCoSo) method to assist decision-makers in selecting a device for Continuous Glucose Monitoring (CGM) that enables effective management of people with diabetes. The CoCoso method is a Multi-Criteria Decision Analysis (MCDA) approach for selecting the best alternative among the available ones, considering the relative importance of criteria. In the current study, seven different types of CGM devices are examined, considering criteria such as accuracy, cost, number of compatible platforms, number of additional features, and setup time. The Preference Selection Index (PSI) method was used to determine the relative importance of these criteria. Sensitivity tests were conducted

1 - Understanding the Value of Retail Accessibility in Private Housing Markets: A Study from Turin, Italy

Marco Del Nibletto, Giulio Zotteri, Marta Bottero, Federico Dell'Anna

The relationship between urban amenities and property values has been widely studied, yet the specific contribution of retail accessibility to housing prices in European urban areas remains underexplored. This paper makes a significant contribution to this field by introducing a new classification of retail categories within the Hedonic Pricing Method and Geographically Weighted Regression (GWR) frameworks. It categorizes retail into five types: shopping, convenience, supermarkets, bars & restaurants, and traditional markets, to capture the influence of the retail landscape on housing values. A key innovation is the use of a gravity-based accessibility index to quantify the proximity of various retail types to residential properties, using a decay parameter that optimizes the explanatory power of retail accessibility. The findings suggest that shopping, bars & restaurants have a positive effect, while convenience retail and traditional markets have a negative impact. The study did not find a significant relationship between housing values and accessibility to supermarkets. GWR was used for the first time in this research domain, providing new insights into the spatial dynamics at play. The study focuses on Turin, Italy, and provides valuable information for urban planners and policymakers regarding the differential impacts of retail accessibility across urban areas. It highlights the importance of strategic support for the retail sector to enhance the value of investments.

2 - Exploring Urban Regulation Effectiveness: Investigating Retailers' Distribution Costs

Negin Jamili, Pieter van den Berg, René de Koster

Governments employ diverse strategies, including financial disincentives, restrictions, and subsidization, to shape urban environments and achieve specific objectives like reducing CO2 emissions. In the Netherlands, policies like time windows and vehicle restrictions are implemented to enhance urban transportation. Time windows reduce inconvenience caused by large trucks during peak hours, improving social sustainability, while vehicle restrictions alleviate traffic problems and pollution, promoting a cleaner and safer urban environment. This research investigates the effectiveness of these regulations. Specifically, we focus on retailers and their distribution and replenishment operations to examine the effects of regulations. So, the concept involves optimizing the operational aspects of the retailer, such as distribution and replenishment, within the framework of specified regulations. The output of this optimization process guides us through gauging the city measures to figure out if they are in line with the goals of regulations. We also explore whether city hubs may be an efficient addition under a given regulatory framework. In the case of confirming the effectiveness of city hubs, subsidizing the city hubs is also an option to address urban transport issues. The result of this study may offer valuable managerial insights into the evaluation of the effectiveness of urban policies and regulations.

3 - Multiple benefits spatial impact assessment for the project Varcities

Sara Biancifiori, Sara Torabi, Adriano Bisello, Patrizia Lombardi

The Varcities Horizon project aims to implement visionary nature-based solutions (VS), which contribute to the shaping of future green cities and the well-being of citizens in seven European cities. The present study aims to promote the replication of these solutions on a local level, providing a decision support tool to guide local administrations with a common baseline. As part of the tool, a spatial impact analysis will be presented, showcasing the positive impacts developed from the project. The theory of multiple benefits considers the positive impacts that can result from a NBS project without ranking or classification. The co-creation strategy for the project was structured into four main stages: co-identification, co-design, co-implementation, and co-evaluation. During the co-design phase, the stakeholders involved in each pilot selected a set of multiple benefits as goals for the development of the visionary solutions. During the co-monitoring phase, the solutions are being monitored through Key Performance Indicators (KPIs). To verify the multiple benefits achieved by the solutions, a validation workshop with stakeholders is proposed, followed by a spatial visualization of the KPIs connected to each Visionary Solution. This will demonstrate the various benefits connected to the solutions. The spatial impact assessment will assist administrations implementing VS, translating the theoretical concept of multiple benefits into a more comprehensible one.

4 - Measuring Urban Smartness: A Comparative Study of European Cities Using Multi-Criteria Analysis

Sandra Milanović, Jelena J. Stanković, Ivana Marjanović

The prevailing and anticipated rates of urbanization are recognized as substantial challenges to the society. Urban areas have been mapped as primary drivers of economic development, however, the rapid expansion of cities in recent decades has raised concerns regarding their sustainability, as evidenced by escalating infrastructural, ecological, and social challenges. Bearing in mind the benefits of smart urban development, this paper aims to assess the level of achieved smartness in European cities using a multicriteria analysis approach. By utilizing data from the latest Eurostat Urban Audit Perception Survey, the research assesses the perceived urban performance by inhabitants, encompassing various dimensions of smart and sustainable urban development. To analyse the diverse attributes of cities' urban performance, a multi-criteria model is developed. This model integrates entropy for determining criteria weights and employs the PROMETHEE method for ranking. Respondents' subjective preferences are measured using a 4-point Likert scale, and responses are quantified for analysis purposes. The resulting rankings are visually presented to identify European urban areas where inhabitants perceive the highest overall levels of smartness and sustainable urban development. The obtained results may serve local self-governments, by offering a diagnostic tool for evaluating the effectiveness of existing smart city initiatives and identifying areas for improvement.

Electric Vehicles within Electric Power Systems

Stream: OR in Energy

Invited session

Chair: Pablo Diaz-Cachinero

1 - Assessing the Capability of Electric Vehicles to Enhance Flexibility of the Chilean Power System

Gabriel Canales, Angela Flores

Chile is actively pursuing an ambitious agenda for the widespread electrification of the transportation sector, establishing that by 2035, 100% of sales for all light and medium-duty passenger vehicles must be zero-emission. The large-scale integration of electric vehicles, while posing substantial challenges in managing the power grid, concurrently presents opportunities to significantly enhance system flexibility. This work analyzes the potential of electric vehicles to augment the flexibility of the Chilean power system. We introduce an operational model for electric vehicles, encompassing both personal vehicles and ride-hailing services, while integrating intelligent charging and discharging modes. The EV operational model is integrated into a unit commitment model, with the objective of assessing the impact of various electric vehicle operation modes on the power system operation. Applying this model to a realistic representation of the Chilean power system towards 2050, we evaluate the potential of electric vehicles in enhancing flexibility metrics. Furthermore, we investigate the influence of the adoption of ride-hailing services on the flexibility provided by the vehicle fleet. This research contributes valuable insights within the context of the Chilean power system, utilizing a realistic representation and considering the evolving landscape of electric transportation.

2 - An Iterative Multistage Model for Electric Vehicle Routing and Charging Management in Road Transportation and Power Distribution Systems

Pablo Diaz-Cachinero, Javier Contreras, Jose Ignacio Muñoz-Hernandez, Mahdi Pourakbari-Kasmaei, Matti Lehtonen

Electric vehicles (EVs) emerge as a promising alternative to fossil fuel-powered vehicles, noted for their zero emissions. As more EVs take to the roads, managing their interaction with road transportation and power distribution systems becomes crucial to meet electrical demand. This study presents a new multistage model that integrates EV delivery routing with energy charging management. The model considers the constraints of EVs and parcel delivery in the road transportation system, while the power distribution system operation is modeled via a linearized AC power flow model including generators and conventional demand. This work considers an EV demand aggregator, whose aim is to find the best strategy in terms of costs and benefits by adjusting EV routing via incentives for availability time and charging EVs at points with the lowest locational marginal prices (LMPs). The model unfolds through three main iteratively interconnected stages. First, delivery allocation and detailed routing are tackled to minimize traveled distances and operational costs. Then, an iterative linkage between the road transportation and energy distribution systems is performed. Finally, a bi-level model is proposed to optimize the charging strategy by the EV demand aggregator in the power distribution system, minimizing costs based on LMPs. Numerical results validate the proposed model with a case study that includes 3,000 EVs within a 284-intersection map and a 119-bus power distribution system.

This study presents a novel approach to schedule surveillance operations for critical undersea infrastructure. The problem addresses the vulnerability of undersea infrastructure to deliberate attacks, natural disasters, accidents and anchor droppage incorporating their associated risks. The aim is to allocate and order the surveillance operations across different levels, including undersea, surface, and aerial activities. There is a trade-off between minimising surveillance operations cost and maximising incident detection. Therefore, the problem is formulated as a novel bi-objective flexible job-shop scheduling model (BO-FJSS) considering operational constraints for multiple types of surveillance assets, such as remotely operated underwater vehicles (ROVs), autonomous underwater vehicles (AUVs), unmanned aerial vehicles (UAVs) and surface vessels. The study also emphasises on the significance of various risk factors, achieved by utilising the Analytic Network Process (ANP) to assess the risks at different depths and incorporating them as weights in the BO-FJSS model. The computational experiments on a specific gas pipeline between the UK and Norway, offer valuable insights into the diverse levels of risks associated with various events within different depth ranges. This information can assist in prioritising risk management strategies and efficiently allocating resources.

2 - A quadtree-based heuristic and variable neighborhood descent for the optimal location of heterogeneous multi-static sonar network

Owein Thuillier, Nicolas Le Josse, Alexandru Olteanu, Marc Sevaux, Hervé Tanguy

In the context of airborne Anti-Submarine Warfare (ASW), we focus here on active sonar systems, i.e. systems based on the transmission and reception of an acoustic wave reflected by the target (echo). Furthermore, our case study involves acoustic buoys, or sonobuoys, which can be classified into three main categories: transmitter-only (Tx), receiver-only (Rx) and transmitter-receiver (TxRx). When transmitter and receiver are co-located - TxRx buoy - we refer to this as monostatic, while when transmitter and receiver are located in two distinct geographical locations, we refer to this as bistatic. A Multistatic Sonar Network (MSN) is therefore defined as a combination of sonar systems in monostatic and/or bistatic configuration. In this context, given a limited number of heterogeneous sonobuoys and probabilistic detection models, we seek to determine the optimal MSN, i.e. the one that maximizes the area covered. To address this issue, we propose a constructive greedy heuristic relying on a QuadTree-based approach (QT) enhanced by a local search through Variable Neighborhood Descent (VND). This heuristic is based on a recursive principle - akin to branch & bound - dividing the area of interest into sectors and accelerating the search for locally optimal positions through judicious computation of upper and lower bounds. Finally, we compare our method with the most efficient Mixed-Integer Linear Program (MILP) in the literature as well as a Simulated Annealing (SA).

3 - Augmenting a Joint Force Dynamic Targeting Decisions

Peter Bovet Emanuel

This study is motivated by optimizing the utilization of military resources within a joint force involved in targeting activities during operations. The weapon-to-target problem (WTA) is type of assignment problem as each target requires a matching with an appropriate weapon and each weapon is a resource within a joint force's targeting enterprise. Engaging high priority targets necessitates consideration including its characteristics, vulnerabilities, and level of protection. Furthermore, one's own weapons must be effective against the specific target to create a desired effect. High priority targets often require expensive weapons with high accuracy which makes these weapons scarce resources. Emerging targets in the battlespace are associated with uncertainties, priorities, compatible weapon types and the corresponding number weapons to a desired effect. The matching of weapon-to-target is constrained by inherent capacities, the protection level of the targets, and subject to probability in the execution of each mission or target engagement. All prioritized targets need to be engaged and neutralized, therefore potentially requiring a re-attack in a second stage. Therefore, the study employed a multi-stage and multi-objective model to replicate a dynamic targeting environment and linearized the probability aspect to enable integer linear programming (ILP) model. The study

1 - Central-Local Governments Cooperate to Pre-Position Relief Supplies for Natural Disaster Response

Cheng-Lin Fong, Tsung-Sheng Chang

Prepositioning of relief supplies is crucial for the timely response to disasters. In a country, central government leads the management of mass casualty incidents (MCIs), while local governments must be able to handle non-MCIs that may occur in their responsible areas. To preposition relief supplies, the central and local governments must determine the number, locations and sizes of facilities, and the amount of disaster relief supplies prepositioned in the facilities. Each local government individually optimizes its prepositioning decisions. However, once an MCI happens, the central government needs to coordinate local governments to offer sufficient suppliers to meet the demand from the affected areas. That is, the central government must take the local governments' prepositioning decisions into account to optimize its nationwide prepositioning decisions. Therefore, this research intends to design incentive schemes that help the central government coordinate the local governments to make optimal prepositioning decisions. To this end, we mathematically model the central government's prepositioning problem, and then propose a solution algorithm based on the model to solve the problem. An empirical study is conducted to verify the proposed mathematical model and solution approach.

2 - Multi-period facility location problem with resource allocation in humanitarian logistics

Yufeng Guo, Etsuko Nishimura

Large-scale natural disasters have caused significant casualties and enormous economic losses. Effectively responding to disasters has become primary challenge for logistics authorities. After a disaster, shortages or over-supply may occur in the resource supply chain. One of the challenges that must be addressed is how to make up for shortages. To rationalise the use of limited resources, decision-makers have to decide facilities' operations and resources allocation based on changes in disaster phases. With this issue in mind, we propose a mathematical model addressing the facility location problem within the context of post-disaster phases across multiple periods, integrating equity, transshipment, and capacity limitations. To validate the mathematical formulation and assess the effect of individual and combined concepts on the foundational model. We conducted a series of numerical experiments using python and commercial solver, Gurobi. The results indicate that the equity primarily influences the maximum unsatisfaction rate on the demand side, while the transshipment predominantly impacts emergency logistics' operations and resources allocation. The limitation of capacity mainly affects transfer ability between emergency logistics centers. Furthermore, we gleaned additional managerial insights through sensitivity analysis of critical parameters, and delineated practical application for integrating our model into disaster management system.

3 - Strategic Decision Support in Disaster Relief Logistics: Stochastic Network Optimization for Efficient Resource Location and Allocation

Katharina Eberhardt, Patricia Fuchß, Sonja Rosenberg, Frank Schultmann

In response to the complex challenges of disaster relief logistics, we present a stochastic network modeling approach to develop insights into strategic facility location, capacity planning, and resource allocation of relief supplies. The primary purpose of the proposed model and numerical experiments is to present a cost-effective logistics network designed to efficiently handle multiple relief items across a spectrum of different crisis scenarios. By incorporating stochastic elements into the analysis, we aim to capture the inherent unpredictability of demand fluctuations and supply chain disruptions. Moreover, our approach centers on optimizing facility sizes to harness economies of scale and refining allocation decisions. To demonstrate the practical applicability of our model, we conduct a computational case study utilizing instances from the German national food stockpiling system. Additionally, we present a sensitivity analysis highlighting the impact of network modifications, crisis intensity, and scale effects on facility location and assignment decisions. The results provide managerial insights and economic considerations for decision-makers, enhancing the resilience and adaptability of cost-effective disaster preparedness and network design strategies.

4 - United Nations Humanitarian Response Depot's Food Support in South Asia via Multi-stage Stochastic Programming

Ruoyu Hu, Douglas Alem, Aakil Caunhye

As one of the largest humanitarian logistics supply chains, the task for United Nations Humanitarian Response Depot (UNHRD) is how to allocate relief aid to save more people who suffered from disasters. This task is particularly challenging in areas like South Asia, where food aid efforts are confronted with complex transportation conditions, significant economic disparities, and the frequent occurrence of disasters, not to mention that relief aid resources are often scarce. In this research, we develop a novel Multi-stage Stochastic Programming (MSP) model to help UNHRD support critical decisions regarding site selection and aid allocation. Differently from the main literature where these decisions are often made within a two-stage paradigm, our three-stage perspective takes into account relief aid donation campaigns that are triggered depending on the disaster impact and its effects. Our objective function maximizes coverage weighted by the population profile, leveraging suitability indicators from locations to enhance strategic decisions on aid distribution. The results overall highlight the role of donated food aid in settings with severe constraints, demonstrating the MSP model's effectiveness in enhancing strategic response through staged information processing. This approach not only illustrates the model's adaptability in complex disaster scenarios but also its capacity to mitigate uncertainties in aid demand coverage, even when increases in coverage are marginal.

Energy transition and operations

Stream: Energy Management

Invited session

Chair: Ece Cigdem Karakoyun

1 - Analysis and Mitigation of Unintended Carbon Emissions from Storage and Demand Response.

Olga Kuryatnikova, Clarisse Dupont, Yashar Ghiassi-Farrokhfal, Derek Bunn

Storage and demand response could provide necessary flexibility to accommodate the influx of intermittent renewable energy and facilitate the low carbon energy transition. However, the operation of these flexible assets may inadvertently intensify carbon emissions, leading to a conflict between profit maximization and environmental impact. We develop a model to characterize the factors causing this effect. Essentially, both storage and demand response act as load-shifting agents (LSAs), and therefore, they indirectly influence emissions. The scope of this influence depends upon the carbon intensity profile of the supply

function in the wholesale market and the round-trip efficiency of LSAs. Some of the insights are surprising, e.g., the more efficient LSAs do not always lead to lower carbon emissions. Next, we propose and analyze several policy instruments aimed at reducing the unintended emissions caused by LSAs. Finally, using data from the Dutch market, we simulate the impact of LSAs and the emission mitigation instruments. We find that in 2019, simply adding LSAs to the market would reduce the total carbon emission. Conversely, in 2022, some LSAs, such as pumped hydro storage and lithium-ion batteries, would increase the emission if no CO₂ mitigation instruments were applied.

2 - Optimal Hour-Ahead Commitment and Storage Decisions of Wind Power Producers

Ece Cigdem Karakoyun, Harun Avci, Tim Huh, Ayse Selin Kocaman, Emre Nadar

Renewable energy generators often rely on their battery deployments to meet their dispatch or purchase commitments in electricity markets. However, the literature optimizing the commitment decisions with storage considerations is scarce. In this paper, we study the joint energy commitment and storage problem for a wind farm paired with a battery. The power producer decides, in each hour of a finite planning horizon, how much energy to commit to dispatching or purchasing for the next hour as well as how much wind energy to generate and how much energy to charge or discharge. The power producer pays a penalty cost if she does not fully meet her commitment. We model this problem as a Markov decision process with random electricity price and wind speed. We prove the optimality of a state-dependent threshold policy under positive prices. This policy partitions the state space into several disjoint domains, each associated with a different action type, such that it is optimal to bring the storage and commitment levels to a different threshold pair in each domain. We employ our structural results to develop a heuristic solution procedure in a more general problem where the price can also be negative. Numerical results for data-calibrated instances indicate the high efficiency and scalability of our solution procedure: it yields optimal or near-optimal solutions with a speedup of two orders of magnitude over the standard dynamic programming algorithm.

3 - Conformal Prediction for Stochastic Decision-Making of PV Power in Electricity Markets

Tarek Alskaf

The increasing integration of solar photovoltaic (PV) power poses challenges for power system operation. Accurate forecasts of PV power are both financially beneficial for electricity suppliers and necessary for grid operators to optimize operation and avoid grid imbalances. This talk will explore a framework utilizing conformal prediction (CP), an emerging probabilistic forecasting methodology, to assist decision-making for PV power market participants on the day-ahead market (DAM). It will begin by demonstrating how machine learning models can be employed to construct the point predictions based on weather forecasts. Subsequently, various variants of conformal prediction are introduced to quantify the uncertainty of these predictions. The talk will then explore the application of several market bidding strategies, including trust-the-forecast, worst-case, Newsvendor and expected utility maximization, to facilitate decision-making for market participants on the DAM using CP methods. Through a case study in the Netherlands, it will highlight how CP when combined with certain bidding strategies can lead to increased profit with minimal energy imbalance, outperforming classical probabilistic forecasting methods, such as linear quantile regression. The talk will conclude by highlighting the need to expand the framework to cover other short-term markets, namely intra-day markets.

4 - Efficient representations for the scheduling of aggregate charging power of battery electric vehicles

Simon Tindemans, Nanda Kishor Panda

Battery Electric Vehicles (BEVs) must connect to a charging point to recharge their batteries. They are often plugged in for longer than they need to gain sufficient charge, so there is scope for smart scheduling of charging within the available window. Moreover, as the maximum charging power increases, this flexibility potential increases, but so

does its necessity: collectively, charging vehicles can easily overload the capacity of the local electricity grid.

Aggregators that control the charging of BEVs use smart charging to optimize the aggregate power demand, for example, to trade on electricity markets. However, even in a fully deterministic setting, direct scheduling of large numbers of BEV charging sessions (tens of thousands) becomes a significant computational burden, because the number of variables increases linearly with the number of vehicles. It would be better to directly represent the flexibility of the aggregate power, but calculating the aggregate flexibility envelope is in general an NP-hard problem.

I will present a flexibility representation (UL-flexibility) that can efficiently calculate the exact aggregate envelope, for the special case where all vehicles remain connected during a specified interval. This representation involves only 2T parameters and can efficiently be used to construct the polytope that constrains the aggregate power consumption of a fleet - independent on the number of BEVs.

1 - Scheduling Large-Scale Infrastructure Renovation Projects Minimizing Emissions Using a Hybrid Genetic Algorithm

Robbert Bosch, Patricia Rogetzer, Wouter van Heeswijk, Martijn Mes

The safety and accessibility of infrastructure such as bridges and quay walls in cities is important for the everyday life of its inhabitants. However, due to wear and tear over the years, these infrastructure pieces need to be maintained or renovated. These large-scale renovation projects generate CO₂ emissions by the material production chain, the logistics surrounding the supply of material and equipment and removal of waste, and the increased traffic due to traffic diversions. The magnitude of these emissions can be difficult to predict, especially when multiple projects are executed in parallel due to time pressure. Parallel execution of projects may yield economies of scale regarding logistics but can also cause excessive congestion. Optimizing the schedule of these projects by finding the right combinations of projects to perform simultaneously can reduce the total emissions and reduce project delays. To aid decision-making, we use multi-objective optimization to minimize total emissions while simultaneously reducing project delays. We present a Hybrid Genetic Algorithm to produce a partial Pareto frontier of schedules for large-scale urban infrastructure renovation projects. This research applies the described solution method to the problem of renovation of bridges and quay walls in Amsterdam. The results illustrate the trade-off between sustainability and tempo of renovations.

2 - Towards energy-aware daily production optimization

Pieter Leyman, Stijn De Vuyst

Imagine a world in which production companies do not have to worry about their energy supply. Not just because they have their own renewable energy sources (e.g., solar panels, wind turbines) and energy storage (e.g., industrial batteries), but more importantly because their entire production system has been designed and is managed to optimally use the available electrical and thermal energy. In essence, focus has shifted from optimizing production goals and subsequently determining where and how to get energy from, to optimizing production and energy goals together. As a result, production is more sustainable and cheaper in terms of energy costs, without sacrificing capacity. Unfortunately, the energy crisis has proven that we are presently far removed from such an ideal world.

We will provide a holistic roadmap on energy-aware daily production scheduling, in which the technological aspects of energy supply and storage are taken into account, and are furthermore matched with energy demand from production. We will subsequently zoom in on a specific problem, namely the order acceptance and scheduling (OAS) problem, with the inclusion of electricity grid costs based on day-ahead prices. Aside from a mathematical model, we will discuss a meta-heuristic algorithm, and compare the performance of both on a small dataset.

3 - Variability reduction in semiconductor manufacturing using machine learning and explainable AI

Venugopal Ramadasu, Fabian Lindner, Gerald Reiner, Germar Schneider, Gerhard Luhn

The impact of variability on a production system in terms of flow time and work in progress is a well-known problem. Recent research works investigating the application of machine learning (ML) models on production data to improve process performance have shown promising results. Drawing inspiration from such works, in the first part of the study we do partial replicative research and apply existing ML models to identify the sources of variability such as machine parameters, defects, product routing and so on that lead to increased flow time in a semiconductor manufacturing plant. Using the production data for a work center in the wafer production process, we identify the critical parameters in the work center that influence the flow time using ML algorithms such as random forest, neural networks and gradient boosting. To enhance the interpretability of the results, we apply explainable AI (XAI) approaches such as Shapley Additive Explanation (SHAP). As a second step, the results will be presented to process experts to derive actions that can reduce the variability in the process and thus enhance the efficiency in resource utilization. Through our work, we expect, on the one hand, to reinforce the potential benefits of using ML models to understand and improve production processes, and on the other hand, to increase the trust of experts on the use of ML models and to leverage their knowledge to tackle the issues they face in manufacturing.

4 - Reducing scope 2 emissions through carbon-aware flow-shop scheduling

Andrea Mencaroni, Dieter Claeys, Stijn De Vuyst, Birger Raa, Pieter Leyman

Detailed scheduling has traditionally been optimized for the reduction of makespan and manufacturing costs. However, growing awareness of environmental concerns and increasingly stringent regulations are pushing industry towards reducing the carbon footprint of its operations. Scope 2 emissions, which are the indirect emissions related to the production and consumption of grid energy, are in fact estimated to be responsible for more than one-third of the global GHG emissions. In this context, carbon-aware scheduling can serve as a powerful way to reduce manufacturing's carbon footprint by considering the time-sensitive carbon content of grid energy and the availability of on-site renewable energy.

This study introduces a carbon-aware flow-shop scheduling model designed to reduce scope 2 emissions. The model is formulated as a mixed-integer linear problem, taking into account the forecasted grid energy generation mix and available on-site renewable energy, along with the set of jobs to be scheduled and their corresponding energy requirements. The objective is to find an optimal day-ahead schedule that minimizes scope 2 emissions. The problem is addressed using a dedicated memetic algorithm, combining evolutionary strategy and local search.

Results from a comprehensive case study confirm that by considering the dynamic carbon content of grid energy and on-site renewable energy availability, significant reductions in carbon emissions can be achieved.

Sustainable Operations

Stream: Sustainable Supply Chains

Invited session

Chair: Jens Brunner

1 - Capitalizing on the Bill-of-Materials to efficiently respond to sustainability challenges

Renske Prins, Jan van Dalen, Rob Zuidwijk

Regulatory requirements and market demand necessitate that companies accurately report on sustainability, monitor risks, and undertake actions to reduce emissions and improve ethical performance (SEC, 2022; CSR Germany, 2023; European Commission, 2023; Khan et al., 2021). This can be a daunting task in a complex global economy. High-level strategies and highly detailed emission reduction initiatives have been suggested (Bressanelli et al., 2022; Preut et al., 2021; Izmirlı et al., 2021; Andersen and Jaeger, 2021; Bogers, 2011; Puertas et al., 2008; Frias et al., 2015; Karell and Niinimäki, 2020; Akadiri and Olomlaiye, 2012). However, addressing this challenge requires scalable solutions. This paper shows how the Bill-of-Materials (BoM), as the skeleton of a company's operations and supply chain, can be an instrument for such scalability. By enhancing the BoM with the emissions and activity data needed to guide these important initiatives, companies can improve accurate and continuous reporting. The enhanced BoM graphs are used for emission optimization and product carbon footprint calculation, and guide business decisions about the focus of emission reduction efforts. Utilizing network analysis techniques, the study demonstrates the effectiveness of an enhanced BoM in scaling sustainable initiatives and complying with regulations, thereby bridging the gap between high-level sustainability strategies and detailed emission reduction initiatives.

2 - Learning Priority Indices for Energy-Aware Scheduling of Jobs in Flow Shops with Batch Processing Machines

Daniel Schorn, Lars Moench

A scheduling problem for a two-stage flexible flow shop with parallel batch processing machines (BPMs) is considered. Here, a batch is a group of jobs that are processed at the same time on a single machine. This problem is motivated by process conditions found in semiconductor wafer fabrication facilities (wafer fabs). Jobs having unequal ready times are assumed. Moreover, critical queue time constraints, i.e. maximum time lags, are taken into account. A blended objective function combining the total weighted tardiness (TWT) and the total electricity cost (TEC) under a time-of-use (TOU) tariff is considered. A genetic programming (GP) procedure is designed to automatically discover priority indices for a heuristic scheduling framework. Results of computational experiments based on randomly generated problem instances are reported that demonstrate that the learned priority indices lead to high-quality schedules in a short amount of computing time.

3 - Environmental and operational optimization of Central Sterile Supply Departments in Danish and German hospitals

Lukas Messmann, Robin Schlembach, Jens Brunner, Sebastian Schiffels, Axel Tuma

Central Sterile Supply Departments (CSSD) play a critical role in the operation of hospitals and for their overall environmental footprint. Operationally, the batching of jobs and their scheduling and allocation to washer-disinfectors and sterilizers is a complex decision-making problem, with CSSDs being potential bottlenecks in surgery scheduling. Environmentally, on the one hand, CSSDs enable the reusing of surgical and other sterile equipment and thus help to reduce the environmental impacts of production and waste treatment associated with alternative disposable solutions. On the other hand, CSSDs themselves consume substantial amounts of electric and thermal energy, chemical cleaning agents, water, and disposable equipment (e.g., face masks,

gloves, fleeces). Critically, operational and (various) environmental objectives are often strongly conflicting. In this work, we develop a two-stage batch-scheduling flexible flow shop model of a CSSD, which is parameterized with Life Cycle Assessment-based environmental data. The model and its parameters are validated by real-world cases of CSSDs in German and Danish hospitals. We anticipate the model to identify possible compromise solutions between conflicting objectives (e.g., by adjusting utilization rates and time-temperature profiles in autoclaves), thereby concurrently contributing to the operational efficiency and sustainable transformation of hospitals.

4 - Driving Sustainability through Symbiotic Supply Chains: An Operations Research Modeling Framework

Susana Relvas, Mafalda Ivo de Carvalho, Vânia Veloso, Bruna Mota, Ana Carvalho, Ana Barbosa-Povoa

In contemporary discourse, the pursuit of sustainability underscores the profound impact of supply chains (SC) on environmental dynamics. Despite efforts to manage direct greenhouse gas emissions, the less tangible indirect emissions require a comprehensive approach to emissions management. Industrial symbiosis (IS) in a context of Supply Chain Management that results in Symbiotic Supply Chains (SymSC) is a possible solution that yet remains underexplored. This work proposes a novel definition of Symbiotic Supply Chains (SymSC), building upon existing definitions and frameworks. It emphasizes the pivotal role of collaboration in the share of flows under the nexus of material-energy-water in a network involving multiple SCs. Given their complexity, SymSCs require detailed planning and management which can be facilitated with the integration of Operations Research techniques. We provide the basis for modeling guidelines to optimize SymSC decisions, which build on the existing IS models available in the literature. This study contributes to the understanding of symbiotic relationships across SCs, focusing on key features characterizing optimization models in the context of IS. Recognizing that SymSCs hold promise in advancing the sustainability agenda, a roadmap for future research and decision-making tools to enhance sustainability performance in the context of SymSC is provided.

Invited session

Chair: Gerhard-Wilhelm Weber

Chair: Olabode Adewoye

Chair: Milagros Baldemor

1 - Allocation and routing of service technicians with different skill levels

Xingyi Wang, Gudrun Kiesmuller, Rainer Kolisch

Typically, companies for home appliances offer after-sales services, especially repair services, to their customers. One of the challenging planning problems that has to be solved in this context is the allocation and routing of service technicians that satisfy customers' service requests. In this paper, we consider heterogeneous technicians with two different skill levels. Junior technicians have less experience and, therefore, may fail to repair the appliance successfully, and senior technicians will repair the appliance successfully. In case of a failed service repair by a junior technician, a second visit by a senior technician is necessary. We formulate the problem as a sequential decision problem, where new customer requests arrive in each period, and decisions on the allocation and routing of service technicians are made at the beginning of each period. While the customer requests are known for the

current period, future requests and their locations are unknown. The objective is the minimization of the total expected technicians' travel and customers' waiting costs. Several heuristic methods are proposed to solve the multi-period problem. We perform an extensive numerical study comparing the performance of the heuristic methods in different problem settings and provide managerial insights.

2 - Enhancing on-time order fulfillment for autonomous order picking and delivery systems of online retailers

Zhengmin Zhang, Zhe Yuan

Many online retailers start to fulfill orders within one hour or even minutes to guarantee a good customer experience. This study analyzes the on-time order fulfillment problem for an autonomous order picking and delivery system in online retailers. We draw inspiration from Meituan's pioneering solution, "Autonomous micro-warehouse and delivery", in which micro-warehouse robots are used for order picking, and delivery robots are used for transporting orders to destinations. We investigate the dynamic priority policy to facilitate efficient task allocation for different order classes, which ensures prompt service for high-priority orders and attentive handling of low-priority orders with extended waiting times.

We develop a dynamic priority-based queueing network to model the system and propose an AMVA-based approximation method to solve it. Numerical experiments validate the analytical model, providing valuable insights into operational efficiency. This paper makes the following contributions: (1) We are among the earliest to investigate autonomous order picking and delivery systems using queueing networks. We propose a new approximation method to solve the proposed nested queueing network with dynamic priority. (2) We outline procedures for determining the optimal numbers of micro-warehouse robots and delivery robots, considering the order fulfillment time requirements. (3) We find that the use of dynamic priority can improve the on-time order fulfillment rate.

3 - Grey systems theory and a Markov chain model MCGM (1,1) applied to demand forecast for a 3PL provider

Francisco Trejo, Rafael Torres Escobar

Post-pandemic logistics showed that just-in-time was not always the most successful supply alternative. The effect in the supply chain was a disruption, causing scarcity of material, delays in deliveries, and capacity constraints in transportation. This paper proposes to answer whether the amount of data or high level of uncertainty exist. The ability of models created with large amounts of data may be not necessarily the answer. The proposal is a novel alternative forecast model when the amount of data is not available (< 4 records) and integrates the past demand as a Markov Chain and offers a model's characterization to discriminate a set of data that is suitable for the Grey Systems Theory and a Markov Chain Grey Model MCGM (1,1). The model: 1) incorporates the past demand behavior, 2) establish the transition probability matrix, 3) defines enhanced forecast model through the GST GM (1,1), 4) develops the forecast, 5) measure its performance. The performance measurement was MAPE. The results exceed other models and methodologies such as: exponential smoothing, moving average and linear regression. The MAPE with the traditional methods was 6.58% vs. the MCGM (1,1) was 2.28% and provided a forecast range comparable to ARIMA.

Chair: Paolo Toth

1 - Carousel Greedy Algorithm for the Minimum Stretch Spanning Tree Problem

Carmine Cerrone, Bruce Golden

The Minimum Stretch Spanning Tree Problem (MSSTP) is a variant of the classical minimum spanning tree problem. Consider a simple, connected, undirected, and unweighted graph $G=(V, E)$, where V is the set of vertices and E is the set of edges. The objective of MSSTP is to identify a spanning tree $T=(V, E')$ within G that minimises the stretch, i.e., reduces the maximum distance in the spanning tree between adjacent nodes in the original graph [1]. This problem has practical applications in areas such as distribution systems, network design, transportation networks, sensor networks, phylogenetic tree reconstruction, and parallel machine architectures. This study introduces a promising and efficient Carousel Greedy (CG) algorithm for tackling the MSSTP. The CG algorithm is a generalised greedy algorithm designed to address the conventional limitations of greedy strategies [2]. We will show that our CG algorithm outperforms the General Variable Neighbourhood Search (GVNS) in terms of solution quality, computational time, and consistency across benchmark instances.

[1] Kardam, Y. S., Srivastava, K., & Marti, R. (2023). General variable neighbourhood search for the minimum stretch spanning tree problem. *Optimization Letters*, 17, 2005-2031.

[2] Cerrone, C., Cerulli, R., & Golden, B. (2017). Carousel Greedy: A generalised greedy algorithm with applications in optimisation. *Computers & Operations Research*, 85, 97-112.

2 - From Incremental Transitive Closure to Strongly Polynomial Maximum Flow

James Orlin, Daniel Dadush, Aaron Sidford, Laszlo Vegh

The best strongly polynomial bound for maximum flows in a graph with n nodes and m arcs is the $O(nm)$ bound by Orlin (STOC 2013). His algorithm runs in $O(nm)$ time for graphs that are suitable sparse. King, Rao, and Tarjan (J. Algorithms 1994) had already established the $O(nm)$ run time for all other networks.

Strengthening Orlin's approach, we present a black-box framework that makes any weakly polynomial maximum flow algorithms to strongly polynomial. The algorithm relies on using Italiano's data structure for maintaining an incremental dynamic transitive closure, which runs in $O(nm)$ time. Surprisingly, the remaining operations take much less time, except in the most dense networks. If one can improve the run time for dynamic transitive closure, then one can speed up the running time for the max flow problem as well. We also obtain improved running times for a range of special cases including instances with a bounded number of arcs with finite upper capacity and instances with bounded tree depth.

3 - PathWise 1.0: a software library for the Resource Constrained Shortest Path

Matteo Salani, Saverio Basso

In this paper, we introduce PathWise 1.0, a versatile dual licensed library addressing the Resource Constrained Shortest Path Problem (RCSPP), a fundamental and hard combinatorial problem.

PathWise is capable of modeling and solving a variety of standard RCSPPs implementing state-of-the-art algorithms. The library interfaces with both C++ and Python, easing the task of modeling customized problems with minimal programming required.

Algorithmically, the latest version presents parallel implementations of both exact and heuristic algorithms. Particularly, heuristic algorithms are integrated into a competitive ensemble framework, boosting their effectiveness. Moreover, this release highlights an enhanced bi-directional dynamic programming technique. The joining procedure, usually a time-intensive aspect of the algorithm, now utilizes binary search and Pareto frontier exploration, resulting in notable performance improvements.

We conducted computational experiments using instances from literature, encompassing scenarios featuring a singular resource constraint across cyclic networks and large acyclic networks. We present findings related to instances with multiple resource constraints within cyclic networks.

The flexible parameterization showcases how users can easily model and efficiently resolve multi-constrained problems. To aid comprehension, we provide a tutorial on a column generation algorithm, utilizing PathWise as the solver for the pricing problem.

4 - An improved variant of the Iterated Inside Out algorithm for solving the optimal transport DOTmark Instances

Federico Della Croce, Roberto Baretto, Rosario Scatamacchia

The optimal transport (OT) is a paradigmatic network problem and consists in finding the minimum cost transportation plan that moves quantities of a single item from a set of sources to a set of destinations, where, for each pair source/destination (i,j) , a unit transportation cost holds. The interest in OT has been renewed lately in artificial intelligence applications where a set of instances, called DOTmark, is nowadays the benchmark for OT. Recently, a new exact algorithm for solving OT, called iterated Inside Out (IIO), has been proposed. The strength of this method relies on the fact that potentially many pivoting operations are performed for each computation of dual multipliers and reduced costs. Here, we propose a variant of IIO specifically tailored to the DOTmark instances. This variant solves these instances exploiting the peculiar structure of the transportation costs: these costs depend on the couple of indexes (i,j) of the related variables and present strong regularity in the way they increase or decrease according to a change of index i or j . Given a basic solution, the described structure of costs enables the algorithm to predict from scratch the positivity of a huge set of reduced costs, thus avoiding their computation. Also, it enables to detect the presence of non basic variables with negative reduced costs within a reduced subset of variables. Computational results indicate that this approach is largely superior to the current state of the art algorithms.

Mathematical Optimization for Counterfactual Explanations

*Stream: Mathematical Optimization for XAI
Invited session*

Chair: Jonas Ramirez-Ayerbe

1 - Counterfactual Explanations for Linear Optimization Problems

Jannis Kurtz, Ilker Birbil, Dick den Hertog

In recent years, there has been a rising demand for transparent and explainable machine learning (ML) models. A large stream of works focuses on algorithmic methods to derive so called counterfactual explanations (CE). Although significant progress has been made in generating CEs for ML models, this topic has received minimal attention in the Operations Research (OR) community. However, algorithmic decisions in OR are made by complex algorithms which cannot be considered to be explainable or transparent. In this work we argue that there exist many OR applications where counterfactual explanations are needed and useful. We translate the concept of CEs into the world of linear optimization problems and define three different classes of CEs: strong, weak and relative counterfactual explanations. For all three types we derive problem formulations and analyze the structure of it. We show that the weak and strong CE formulations have some undesirable properties while relative CEs can be derived by solving a convex optimization problem. We test all concepts on a real-world diet network and we show that relative CEs can be calculated efficiently on NETLIB instances.

2 - Finding Regions of Counterfactual Explanations via Robust Optimization

Donato Maragno

Counterfactual explanations play an important role in detecting bias and improving the explainability of data-driven classification models. A counterfactual explanation (CE) is a minimal perturbed data point for which the decision of the model changes. Most of the existing methods can only provide one CE, which may not be achievable for the user. In this work, we derive an iterative method to calculate robust CEs, i.e., CEs that remain valid even after the features are slightly perturbed. To this end, our method provides a whole region of CEs allowing the user to choose a suitable recourse to obtain a desired outcome. We use algorithmic ideas from robust optimization and prove convergence results for the most common machine learning methods including decision trees, tree ensembles, and neural networks. Our experiments show that our method can efficiently generate globally optimal robust CEs for a variety of common data sets and classification models.

3 - Multistage counterfactual decisions

Emilio Carrizosa, Jasone Ramírez-Ayerbe, Dolores Romero Morales

Counterfactual Analysis is a powerful tool for Explainable Artificial Intelligence. In Supervised Classification, this means associating with each record a so-called counterfactual decision, i.e., an instance close to the record (closeness measured by an appropriate and context-dependent dissimilarity) and whose probability of being classified by a given classifier in the positive (desired) class is high. In other words, the counterfactual analysis is a reference for a given individual: how he/she should minimally change to improve the probability of being classified in the positive class. While the literature has focused on the case of finding one counterfactual, we propose in the talk how to address the problem in which a sequence of k decisions, gradually increasing the probabilities of positive, and implying an acceptable cost at each stage. A mathematical optimization model is considered and theoretical properties are derived.

4 - One-for-many Counterfactual Explanations by Column Generation

Jasone Ramírez-Ayerbe, Andrea Lodi

We consider the problem of generating a set of counterfactual explanations for a group of instances, with the one-for-many allocation rule, where one explanation is allocated to a subgroup of the instances. For the first time, we solve the problem of minimizing the number of explanations needed to explain all the instances, while considering sparsity by limiting the number of features allowed to be changed collectively in each explanation. A novel column generation framework is developed to efficiently search for the explanations. Our framework can be applied to any black-box classifier, like neural networks. Compared with a simple adaptation of a mixed-integer programming formulation from the literature, the column generation framework dominates in terms of scalability, computational performance and quality of the solutions.

1 - A hybrid resampling method for imbalanced classification problem

You-Jin Park

Classification has been widely used to categorize the existing instances (i.e., data points) and predict the new instances in various machine learning applications such as fraud detection in financial sector, fault and defect detection in manufacturing industry, and medical diagnosis, etc. However, most classification algorithms have been developed under the assumption that the data distribution of among classes is balanced even though unequal class distributions are quite common. So, the class imbalance problem may affect the performances of many machine learning tasks. Furthermore, the class overlap problem occurs when some instances are located in a certain common region in the data space and it also has a significant impact on the performance in imbalanced classification problems. Thus, in this study, we propose a new hybrid resampling algorithm to improve the performance of imbalanced classification problem by resolving both class imbalance and class overlap problems in imbalanced data simultaneously. In particular, we propose a class impurity measure based on k -nearest neighbor (k -NN) algorithm for adaptively oversampling and under-sampling. To demonstrate the effectiveness of the proposed method, comprehensive experiments are executed on forty imbalanced datasets with considering four classifiers and three classification performance measures. [This work has been supported by the General Research Program funded by NSTC, Taiwan (Grant No. NSTC 110-2221-E-027-106-MY3)]

2 - Context-aware processing rate guided production scheduling: a forecasting embedded branch-and-price heuristic method

Yige Sun, Sai-Ho Chung, Tsan-Ming Choi

Production scheduling seeks to identify effective job execution plans on machines to enhance overall operational efficiency. Prior studies in this area usually assume job processing rates (JPRs) to be constant. However, based on our analysis of real-world production data, multiple factors such as machine use, operator skills, material supplies, and the processing of prior jobs may influence the actual processing of a job in manufacturing operations. To catch the effect of production variabilities and improve scheduling solutions, we introduce a measure named context-aware processing rate (CAPR) in production scheduling. Based on this measure, a novel deep learning-empowered CAPR-guided scheduling approach is developed. Specifically, the CAPR is predicted for each processing context produced along with the pricing process. The CAPR is used to find beneficial allocation and sequencing of jobs to operators and machines with an efficient labelling algorithm. Experiments based on real-world data from our studied printing company show that the proposed method enables a substantial decrease in overall job completion time.

3 - The Sound of Emotions: An Artificial Intelligence Approach to Predicting Emotions from Musical Selections

Ron Hirschprung, Ori Leshman, Chen Hajaj

Music in the current digital era is consumed primarily on-demand, for example by streaming from Spotify or YouTube, rather than by broadcasting, for example, by listening to a radio station. A strong correlation has been found between music and emotions. Hence, with our ability to select our own music and the availability of artificial intelligence (AI) tools, the importance of music emotion recognition (MER) is significant. This research proposes a novel methodology for predicting emotions from a musical piece based on a two-layer AI. The dataset and the process are exceptional in two ways: first, by their qualitative character, which minimized the inherent subjectivity of self-reported emotions, and also the high reliability of the collected data in comparison to other methods such as a questionnaire; and second, by their quantitative character, given $n=9,090$ songs from about 4,447 people. The model succeeded in predicting the primary emotion with accuracy=57% and one of the two leading emotions (the primary and the secondary) with accuracy=75.1%, which is significantly higher than a random guess, and without accommodating demographic factors in the model. We believe this knowledge may be a useful tool for therapists, coaches, teachers, etc. and may also raise public awareness of a potential privacy violation.

4 - SynthEco: A digital system for analyzing multi-dimensional mechanisms of human behaviour in a multi-layered and dynamic geospatial environment

Antonia Gieschen, Raja Sengupta, Duo Zhang, Catherine Paquet, Fares Belkhiria, Laurette Dubé

Synthetic populations are datasets which are created to be statistically representative of a chosen population using census data. They have been used in multiple contexts where researchers are interested in modelling effects on a population or individual level, including health related agent-based models and epidemiology. The SynthEco project aims to provide a platform for researchers to create synthetic populations in the form of an open source Python package available on GitHub through an iterative proportional fitting approach. The package allows for synthetic population creation from any census data and on different geographic levels through a simple plug-in system. Plugins exist for census data from the USA and from Canada, and researchers are invited to contribute their own plugins to create other populations. The use of SynthEco will be demonstrated through several application cases in Montreal, Canada, such as modelling access to healthy food and spatial inequality in financial wellbeing. These are made possible through dataset linkage of the synthetic population with geo-referenced discovery and population cohorts.

1 - Solving the Consistent Travelling Salesman Problem

Juan José Salazar González, Daniel Díaz-Ríos

The consistent travelling salesman problem looks for a minimum-cost set of Hamiltonian routes, one for every day of a given period. When a customer requires service over several days, the service times on different days must differ by no more than a given threshold (for example, one hour). We analyze two variants of the problem, depending on whether the vehicle is allowed to wait or not at a customer location before its service starts. There are three mathematical models in the literature for the problem without waiting times, and this paper describes a new model appropriated to be solved with a branch-and-cut algorithm. The new model is a multi-commodity flow formulation on which Benders' Decomposition helps manage a large number of flow variables. There were no mathematical models in the literature for the variant with waiting times, and this paper adapts the four mathematical models to it. We analyze the computational results of the formulations on instances from the literature with up to 100 customers and three days.

2 - Formulations and Exact Solution Methods for the Undirected Team Orienteering Arc Routing Problem

Wenjin Yan, Elena Fernandez, Ivana Ljubic

Given an undirected graph, we study the team orienteering arc routing problem which asks to find a set of maximum profits routes starting and ending at the depot satisfying the vehicles' travelling time constraints. This problem has many important applications in practice, such as waste collection, snow plowing, and security patrolling, etc. In this article, we propose three new integer linear programming (ILP) formulations with only binary variables for this problem. To solve this problem in large instances, we introduce a Logic-based Benders decomposition (LBBD) and incorporate it into a branch-and-cut framework. We design problem-specific techniques to further improve the performance of the algorithm, such as Benders cuts strengthening approaches, repair heuristics, as well as symmetric breaking constraints

and valid inequalities. In the computational study, we compare the performance of these formulations and different techniques.

3 - A mixed integer formulation and an NSGA-II for the Bi-objective Cumulative Capacitated Vehicle Routing Problem with Priority Indexes

Karina Corona-Gutiérrez, Samuel Nucamendi-Guillén, Iris Martínez-Salazar, Marcos Moreno-Vega

We propose a new mixed integer formulation and an efficient metaheuristic for the Bi-objective Cumulative Capacitated Vehicle Routing Problem considering Priority Indexes (BCCVRP-Pr), a variant of the classical Capacitated Vehicle Routing Problem in which customers are served according to a certain level of preferences by a fixed fleet of heterogeneous vehicles. In this problem, two objectives are minimized: the total latency and the total tardiness of the system. The proposed mathematical formulation (a multilevel network approach) showed its effectiveness by outperforming the previous models presented in the literature, reporting efficient Pareto Fronts for instances up to 25 nodes. Regarding the metaheuristic, we developed a Non-Dominated Sorting Genetic Algorithm (NSGA-II) capable of dealing with larger instances (up to 100 nodes). To evaluate and compare the performance of the metaheuristic procedure against the results obtained by the proposed exact model, we used four performance metrics: the quantity of non-dominated points, the hypervolume, the coverage of two sets, and the elapsed computational time. According to the results, the algorithm showed a compelling performance by providing high-quality Pareto fronts at competitive computational times. Our research provides valuable insights into solving the Cumulative Capacitated Vehicle Routing Problem with priority indexes, suitable for practical applications in industries that require prioritizing customer service.

1 - Latest Development in the MibS Solver for Mixed Integer Bilevel Optimization

Theodore Ralphs

In this talk, we'll discuss the latest improvements in the solution methodology of MibS, an open source solver for solving mixed integer bilevel optimization problems. Recent progress has improved the performance of the solver substantially, as well as adding to its ability to solve related classes of problems. We'll provide some insights into the source of these improvements.

2 - Flowty - a network optimisation solver

Simon Spoorendonk, Bjørn Petersen

Network optimization problems are recognised by their underlying graph(s) and constraints. Examples are within planning & scheduling, vehicle routing, and multi-commodity flow problems. Flowty's solver exploits the graph structure and solves resource constrained shortest path problems to generate variables using a column generation scheme.

Graphs are described as edge sets and a source and target vertices for a path. Paths can additionally be constrained with a set of resources. Constraint modeling is done directly on the vertices and edges of the graphs, the subproblem itself, as well as on traditional mixed integer variables. This allows for very compact models, e.g., set partitioning constraints on vertices and edge design variables in network design problems, and the graph and resource constraints avoids the need for linearisation of constraints (big-M).

The literature has shown that column generation based algorithms are superior for many network optimization problems. The solver combines the familiarity of mixed integer programming models and graph structures with algorithmic speed.

In this talk we will dive into modeling examples in Python, take a quick look under the hood, and present recent performance benchmarks.

3 - Blackbox optimization with the MADS algorithm and the NOMAD software

Sébastien Le Digabel

NOMAD is a free software package for blackbox optimization. It implements the mesh adaptive direct search (MADS), a derivative-free optimization algorithm. NOMAD is designed to solve industrial problems, and therefore it includes several practical features such as constraints handling, the possibility of processing several objectives, noisy evaluations, etc. Several parallel variants of the algorithm are also available. This talk introduces derivative-free and blackbox optimization, the MADS algorithm and the practical use of NOMAD. Realistic test cases will also be discussed.

4 - Hexaly, a new kind of global optimization solver

Frédéric Gardi

Hexaly Optimizer is a new kind of global optimization solver. Its modeling interface is nonlinear and set-oriented. It also supports user-coded functions, thus enabling black-box optimization and, more particularly, simulation optimization. In a sense, Hexaly APIs unify modeling concepts from mixed-linear programming, nonlinear programming, and constraint programming. Under the hood, Hexaly combines various exact and heuristic optimization methods: spatial branch-and-bound, simplex methods, interior-point methods, augmented Lagrangian methods, automatic Dantzig-Wolfe reformulation, column and row generation, propagation methods, local search, direct search, population-based methods, and surrogate modeling techniques for black-box optimization.

Regarding performance benchmarks, Hexaly distinguishes itself against the leading solvers in the market, like Gurobi, IBM Cplex, and Google OR Tools, by delivering fast and scalable solutions to problems in the spaces of Supply Chain and Workforce Management like Routing, Scheduling, Packing, Clustering, and Location. For example, on notoriously hard problems like the Pickup and Delivery Problem with Time Windows or Flexible Job Shop Scheduling with Setup Times, Hexaly delivers solutions with a gap to the best solutions known in the literature smaller than 1% in a few minutes of running times on a basic computer.

1 - New drivers of bankruptcy based on Complex Networks

Jinxian Zhao

This study proposes a novel approach to devise new drivers for bankruptcy prediction using complex network analysis. These drivers are company relational information-based drivers (CRIs) derived from the board of directors' networks with different network configurations. The effectiveness of these new drivers is demonstrated on a dataset of UK companies listed on the London Stock Exchange. Numerical results suggest a significant improvement in predicting corporate

bankruptcy. Our research establishes the impact of incorporating network analysis of company relationships into bankruptcy prediction models. It sets the stage for more sophisticated financial analysis techniques that synergize traditional financial metrics with cutting-edge network analysis, and the advancement holds substantial promise for financial institutions and analysts, providing a more nuanced understanding of corporate bankruptcy risks.

2 - Breaking Barriers: Unveiling Gender Disparities in Corporate Career Paths Using Deep Learning

Cristian Bravo, Yuhao Zhou, Wenhao Chen, María Óskarsdóttir, Collins Ntim, Matt Davison

This study delves into the interplay between gender, professional networking, career-path trajectory, and board director appointments in Canadian publicly traded companies. To obtain our results, we combine multiple publicly available sources into a unique dataset. This dataset (consisting of over 700 Canadian firms covering more than 19,000 senior managers and board members in the 2000-2022 period), charts detailed network information of both senior managers and board members across five key dimensions: education, current and prior employment, and current and prior social engagement. By matching senior managers of both genders based on their career trajectories and backgrounds, and applying Long Short-Term Memory (LSTM) deep learning alongside network analysis, our research uncovers the distinct network influences impacting the board appointment prospects of women versus men. The findings causally demonstrate a "glass ceiling", suggesting that women necessitate more substantial networking credentials than men to secure equivalent corporate board positions, when controlled for career paths and backgrounds. This paper outlines our data compilation process, matching and analytical methodology, presents our empirical results and insights, and the broader implications these hold for policies aimed at encouraging both good corporate governance and gender equality at senior level.

3 - Feature set aggregation using community detection in networks

Christoph Lohrmann, María Óskarsdóttir

In supervised machine learning, especially with high dimensional data, feature selection is an important approach that aims to ensure efficient computation, to achieve a high generalization ability of the learning algorithm, and to support the interpretability of the results. However, the feature subsets selected during feature selection may vary depending on the partition of the training dataset used or the feature selection method deployed. This instability can be a result of including redundant and irrelevant features in some of these subsets or not retaining all relevant features in each of them. The goal of this study is to develop a methodology to find a subset of the relevant features using network science and community detection from among the individual feature subsets. The individual feature subsets will be used to construct a network, where each node represents a feature, and edges between nodes reflect whether two features were selected into the same subset. By considering several runs of a feature selection method, features that appear together often will have a stronger connection, represented by a higher weight on the edge between them. This network will then be analyzed to discover communities, which ideally represent a set of features that is highly connected and, thus, is jointly highly important for the classification task. Optimally, this also allows to visually and/or numerically distinguish the sets of relevant, redundant, and irrelevant features.

Chair: *Cesare Molinari*

1 - Inertial methods beyond minimizer uniqueness

Hippolyte Labarrière

When considering a convex composite minimization problem, it is well known that momentum allows first-order methods to be accelerated both theoretically and numerically. In particular, we know that for a suitable choice of parameters inertial methods ensure fast convergence rates under additional geometry assumptions such as strong convexity. However, the improved convergence results demonstrated in the literature hold only if the function to minimize has a unique minimizer. This extra assumption is limiting, since some common functions (such as the LASSO function or ℓ_1 regularized functions in general) can satisfy some growth condition without having a unique minimizer. The question then arises: is this assumption necessary to prove fast convergence properties?

We propose an approach that aims to avoid this hypothesis while still obtaining fast convergence rates. This strategy allows to extend several known convergence results in the continuous setting (i.e. for dynamical systems associated to inertial schemes). We also provide fast convergence guarantees for the iterates of FISTA (introduced by Beck and Teboulle) and V-FISTA (proposed by Beck) in a relaxed setting, showing that this uniqueness assumption is not required for inertial methods to be efficient.

2 - Adaptive restart of conservative dynamics for convex optimization

Alessandro Scagliotti

In the last years, tools from Dynamical Systems have been fruitfully applied to study existing accelerated optimization methods and to develop new ones. Typically, continuous-time models for accelerated methods are mechanical systems with damping. In this talk, we present an optimization method based on a conservative mechanical system, where the objective function plays the role of the potential energy. Due to the absence of damping, the convergence of this method completely relies on the adaptive restart strategy: a) the initial velocity is set equal to 0; b) by the conservation of the mechanical energy, part of the initial potential energy is transformed into kinetic energy; c) when a proper restart condition is met, the velocity is reset to zero and the kinetic energy at the restart time is instantly dissipated. We prove the convergence result both for the continuous-time method and for the discrete-time version. Finally, we discuss some possible extensions to the nonsmooth case, with particular focus on ℓ_1 -regularization.

[1] A. Scagliotti, P. Colli Franzone. A piecewise conservative method for unconstrained convex optimization, COAP (2022). [2] A. Scagliotti, P. Colli Franzone. A subgradient method with constant step-size for ℓ_1 -composite optimization, BUMI (2023).

3 - Monitoring the Convergence Speed of PDHG to Find Better Primal and Dual Step Sizes

Olivier Fercoq

Primal-dual algorithms for the resolution of convex-concave saddle point problems usually come with one or several step size parameters. Within the range where convergence is guaranteed, choosing well the step size can make the difference between a slow or a fast algorithm. A usual way to adaptively set step sizes is to ensure that there is a fair balance between primal and dual variable's amount of change. In this work, we show how to find even better step sizes for the primal-dual hybrid gradient. Getting inspiration from quadratic problems, we base our method on a spectral radius estimation procedure and try to minimize this spectral radius, which is directly related to the rate of convergence. Building on power iterations, we could produce spectral radius estimates that are always smaller than 1 and work also in the case of conjugate principal eigenvalues. For strongly convex quadratics, we show that our step size rule yields an algorithm as fast as inertial gradient descent. Moreover, since our spectral radius estimates only rely on residual norms, our method can be readily adapted to more general convex-concave saddle point problems. In a second part, we extend these results to a randomized version of PDHG called PURE-CD. We

design a statistical test to compare observed convergence rates and decide whether a step size is better than another. Numerical experiments on least squares, sparse SVM, TV-L1 denoising and TV-L2 denoising problems support our findings.

4 - Stochastic Primal Dual Hybrid Gradient Algorithm with Adaptive Step-Sizes

Claire Delplancke, Antonin Chambolle, Matthias J. Ehrhardt, Carola-Bibiane Schönlieb, Junqi Tang

In this work we propose a new primal-dual algorithm with adaptive step-sizes. The stochastic primal-dual hybrid gradient (SPDHG) algorithm with constant step-sizes (Chambolle et al. 2018, Ehrhardt et al. 2019) has become widely applied in large-scale convex optimization across many scientific fields due to its scalability. While the product of the primal and dual step-sizes is subject to an upper-bound in order to ensure convergence, the selection of the ratio of the step-sizes is critical in applications. Up-to-now there is no systematic and successful way of selecting the primal and dual step-sizes for SPDHG. In this work, we propose a general class of adaptive SPDHG (A-SPDHG) algorithms, and prove their convergence under weak assumptions. We also propose concrete parameters- updating strategies which satisfy the assumptions of our theory and thereby lead to convergent algorithms. Numerical examples on computed tomography demonstrate the effectiveness of the proposed schemes.

Optimal control in organizations

Stream: Optimal Control Theory and Applications

Invited session

Chair: *Gernot Tragler*

1 - Dynamic Pricing, Objective and Subjective Quality, and the Price-Quality Relationship

Régis Chenavaz, Domenico De Giovanni, Pietro De Giovanni

Dynamic pricing and quality are important strategic variables for firms. However, the effects of consumers' objective and subjective quality evaluations on dynamic pricing must be better understood. This article develops an optimal control model of a firm's dynamic pricing and objective quality investment decisions over time. Our research contributes to the literature on the price-quality relationship by providing a dynamic pricing rule and identifying the conditions below which more significant objective and subjective quality may lead to an increase or decrease in the price. Subjective quality impacts dynamic price but not objective quality. In addition, a negative price-quality relationship is possible with both objective and subjective quality. Consequently, the distinction between objective and subjective qualities yields more profitable marketing mix strategies.

2 - Competition between hospitals with age-structured patients and negative congestion effects: a differential game approach

Dominika Machowska, Michael Kuhn, Andrzej Nowakowski, Agnieszka Wiszniewska-Matyskiel, Stefan Wrzaczek

We explore a noncooperative game framework involving two hospitals, where treatment quality suffers under congestion. Recognizing that healthcare demand is significantly influenced by patient age, we incorporate a continuous age distribution into our model. Each hospital aims to determine the optimal treatment (age-structured) intensity that maximizes its objective: for a public hospital, this involves enhancing the cross life-expectancy as measure for the number and quality of treated patients (public hospital); for a private hospital, the goal is to maximize profits based on public payments for treatment. The resulting problem leads to the introduction of differential games with the

closed-loop information structure. The paper formulates conditions for verifying whether a given strategy profile constitutes a Nash equilibrium with the dual closed-loop information structure. The verification theorem is then used to develop a numerical algorithm for determining Nash equilibria in a finite number of steps. The numerical simulations demonstrate how the Nash equilibrium can shift in response to varying socio-economic factors.

3 - The optimal mix of incapacitations and social programs for fighting cartel violence in Mexico

Gernot Tragler, Gustav Feichtinger, Dieter Grass, Jonathan Caulkins, Rafael Prieto-Curiel, Stefan Wrzaczek, Gian Maria Campedelli

Cartels in Latin America pose a significant threat to societal stability and public safety, perpetuating extensive violence and socio-economic disruption. Despite substantial investments in security measures by states like Mexico and the U.S., violence continues to escalate, and the power of cartels remains resilient. In this presentation we examine the effectiveness of current strategies and propose a novel approach using optimal control theory to analyze cartel dynamics. By modelling the allocation of resources between security initiatives and social programs, this study aims to identify an optimal strategy for reducing cartel violence and mitigating its impacts on society. Through this analytical lens, we offer insights into potential avenues for more effective policymaking and resource allocation in the ongoing fight against organized crime.

Preconditioning for Large Scale Nonlinear Optimization

Stream: Advances in large scale nonlinear optimization
Invited session

Chair: Panos Parpas

1 - Loraine - An Interior-Point Solver for Low-Rank Semidefinite Programming

Soodeh Habibi, Michal Kocvara, Michael Stingl

The aim of this talk is to introduce Loraine, a new code for the solution of large-and-sparse linear semidefinite programs (SDPs) with low-rank solutions or solutions with few outlying eigenvalues, and/or problems with low-rank data. We propose to use a preconditioned conjugate gradient method within an interior-point SDP algorithm and an efficient preconditioner fully utilizing the low-rank information. The efficiency will be demonstrated by numerical experiments using the truss topology optimization problems, Lasserre relaxations of the MAX-CUT problems, and the sensor network localization problems. The code is available in Matlab and Julia, and it can be used not only for low-rank problems but also for any linear SDP.

2 - Simba: A Scalable Bilevel Preconditioned Gradient Method for Fast Evasion of Flat Areas and Saddle Points

Nick Tspinakakis, Panos Parpas

First-order methods slow down when applied to high-dimensional non-convex functions due to the presence of saddle points. If, additionally, the saddles are surrounded by large plateaus, it is highly likely that the first-order methods will converge to a sub-optimal solution. A natural way to tackle the limitations of first-order methods is to employ second order information from the Hessian. However, methods that incorporate the Hessian do not scale to large models. To address these issues, we propose Simba, a scalable preconditioned gradient method. The method is very simple to implement. It maintains a single precondition matrix that it is constructed as the outer product of the moving average of the gradients. To significantly reduce the computational

cost of forming and inverting the preconditioner, we draw links with multilevel optimization methods and construct randomized preconditioners. Our numerical experiments and testing against other state-of-the-art methods verify the scalability of Simba as well as its efficacy near saddles and flat areas. We also analyze Simba and show its linear convergence rate for strongly convex functions.

3 - Parallel Neural Network Training via Nonlinearly Preconditioned Trust-Region Method

Samuel Cruz

Neural networks and the data sets used to train them continue to grow in size. Traditional training methods like SGD and Adam require extensive hyperparameter tuning, which is increasingly incompatible with today's demands as current applications require methods that ideally do not need hyperparameter tuning. With this in mind, we investigate additive domain decomposition methods for neural network training. Due to their underlying additive decomposition, our methods are parallelizable, and owing to a trust-region strategy, they largely obviate the need for hyperparameter tuning. Our test results suggest that the investigated methods are potential candidates for efficient neural network training.

4 - Stochastic Mirror Descent for Convex Optimization with Consensus Constraints

Panos Parpas

The mirror descent algorithm is known to be effective in situations where it is beneficial to adapt the mirror map to the underlying geometry of the optimization model. However, the effect of mirror maps on the geometry of distributed optimization problems has not been previously addressed. In this paper we study an exact distributed mirror descent algorithm in continuous-time under additive noise. We establish a linear convergence rate of the proposed dynamics for the setting of convex optimization. Our analysis draws motivation from the Augmented Lagrangian and its relation to gradient tracking. To further explore the benefits of mirror maps in a distributed setting we present a preconditioned variant of our algorithm with an additional mirror map over the Lagrangian dual variables. This allows our method to adapt to both the geometry of the primal variables, as well as to the geometry of the consensus constraint. We also propose a Gauss-Seidel type discretization scheme for the proposed method and establish its linear convergence rate. For certain classes of problems we identify mirror maps that mitigate the effect of the graph's spectral properties on the convergence rate of the algorithm. Using numerical experiments we demonstrate the efficiency of the methodology on convex models, both with and without constraints. Our findings show that the proposed method outperforms other methods, especially in scenarios where the model's geometry is not cap

Cross-dock Door Problems

Stream: Stochastic, Robust and Distributionally Robust Optimization

Invited session

Chair: Laureano F. Escudero

1 - Cross-dock Door Assignment Problem, CDAP, decomposition methodologies

Aitziber Unzueta, Laureano F. Escudero, M. Araceli Garin

The Cross-dock Door Assignment problem (CDAP) consists of using a distribution-docking terminal for helping on supply chain distribution. Given a set of commodities to deliver from origin nodes to destination ones, the products are unloaded using a set of inbound doors, handled in the terminal, and reloaded using a set of outbound doors. The goal is to minimize the transportation cost of the commodities to be handled at the cross-dock. A class of strong lower bounds on the solution value of a Linearized Integer Programming reformulation is introduced for the binary quadratic optimization model to assign origin and destination

nodes to strip and stack doors, respectively, in a cross-dock infrastructure. Strip- and stack-related decomposition submodels are developed by taking benefit of the Integer Linearization Property that appears in the new model. A linear search heuristic is also provided for obtaining feasible solutions by exploiting the special structure of the problem. We present an extensive computational study on a testbed of 55 instances to show that the proposed joint scheme for lower bounding and feasible solution providing is very efficient.

2 - Cross-dock Door Design Problem, CDDP, under uncertainty

M. Araceli Garin, Laureano F. Escudero, Aitziber Unzueta

The Cross-dock Door Design Problem (CDDP) consists of deciding on the number and capacity of inbound and outbound doors for receiving product pallets from origin nodes and exiting them to destination nodes. The uncertainty, realized in scenarios, lies in the occurrence of these nodes, the number and cost of the pallets, and the capacity's disruption of the doors. The CDDP is represented using a stochastic two-stage binary quadratic model (BQM). The first stage decisions are related to the cross-dock infrastructure design, and the second stage ones to the node-to-door's assignments. This is the first time, as far as we know, that a stochastic two-stage BQM has been presented for minimizing the construction cost of the infrastructure and its exploitation expected cost in the scenarios. Given the difficulty of solving this combinatorial problem, a mathematically equivalent MILP formulation is introduced. However, searching an optimal solution is still impractical for commercial solvers. Thus, a scenario cluster decomposition-based matheuristic is introduced to obtain feasible solutions with small optimality gap and reasonable computational effort. A broad study to validate the proposal gives solutions with a much smaller gap than the ones provided by a state-of-the-art general solver. In fact, the proposal provides solutions with a 1 to 5% optimality gap, while the solver does it with up to a 12% gap, if any, and requires a wall time two orders of magnitude higher.

3 - Cross-dock Door Design Problem, CDDP, Multi-horizon Distributionally Robust Optimization

Laureano F. Escudero, M. Araceli Garin, Aitziber Unzueta

Distributionally robust optimization (DRO) is motivated as a counterpart of the usually unknown underlying probability distribution (PD) followed by the uncertainty in dynamic problems. An approach is presented for the highly combinatorial Cross-dock Door Design Problem (CDDP) solving to decide the number and nominal capacity of the strip and stack doors. The strategic uncertainty is represented in a finite set of stagewise-dependent scenarios and the operational one is done in a finite set of stage-dependent scenarios. It is assumed the availability of a Nominal Distribution (ND) for the realization of the strategic parameters in the immediate successors set of any node, and a ND of the realization of the operational parameters in the stages through the multi-horizon scenario tree. Those ambiguity sets are obtained from the projections of appropriate perturbations of the cumulative distribution functions of the ND realizations in a set of modeler-driven PDs, where the Wasserstein distance is satisfied for a given radius. A mixed binary quadratic DRO-MH modeling paradigm is presented to consider the strategic and operational ambiguity sets in CDDP. The aim is to minimize the overall highest expected DRO cost in the nodes, among the ambiguity set members, subject to the constraint system for each one.

1 - Optimization and allocation for connection scheduling problems

Laura Davila-Pena, Peter Borm, Ignacio García-Jurado, Jop Schouten

This work analyzes so-called connection scheduling problems (CSPs), a type of interactive Operations Research problem that combines elements from minimum cost spanning tree problems and sequencing problems. Given a graph, our goal is twofold: firstly, to establish an optimal connection order among players to minimize the overall cost of connecting them to a source, and secondly, to develop a cost allocation strategy for this optimal order among the involved players. We focus specifically on CSPs on trees, for which we propose a recursive solving method integrated with an allocation approach.

2 - Game theoretical approach to determine feature importance

Dani Samaniego, Laura Davila-Pena, Alejandro Saavedra-Nieves

In the last years, the usage of Shapley value is being extended through machine learning algorithms as a method to determine the importance of a feature on its contribution to a certain target value. This is done by defining a cooperative game where features play the role of voters. In this talk we will focus in the need of using a predictor to define the game and its consequences. We will point out other directions in order to obtain the importance of the features in a more robust way. Also we will comment real world use cases where the feature importances plays a key role.

3 - Uncertain Preferences to deal with the Framing Effect in the Graph Model for Conflict Resolution

Deoclecio Castro, Leandro Rêgo

In this article, our goal is to present a method that enables us to perform an analysis using the Graph Model for Conflict Resolution (GMCR) in conflicts scenarios where the preferences of decision makers show inconsistencies due to the Framing Effect. More specifically, we consider a GMCR with two decision makers who presented different preferences when, during the elicitation process, they were confronted with the same problem framed in two distinct ways. This behavior is inconsistent with Decision Theory and may be explained by the boundaries of human rationality. Our approach uses uncertain preferences to address the inconsistencies arising from the Framing Effect.

4 - Simple games with minimum

Sascha Kurz, Dani Samaniego

Every simple game is a monotone Boolean function. For the other direction we just have to exclude the two constant functions. Here we consider simple games with minimum, i.e., simple games with a unique minimal winning vector. We present enumeration results as well as formulas for their dimension.

Applications of conic optimization

Stream: Conic Optimization: Theory, Algorithms, and Applications

Invited session

Chair: [Julio C. Góez](#)

1 - The exponential cone: machine learning and the projection algorithm

Henrik A. Friberg

The exponential cone is an absolute beast with respect to its usages in mathematical modeling, and has proven to be a computational stable and high-performant element of the MOSEK optimization core. In this talk we will explore some of its surprising use cases, e.g. in machine learning, before unveiling the successful story of the "projection onto the exponential cone" algorithm. The Moreau decomposition theorem, the KKT conditions, the convex analysis book by Rockafellar, unconstrained root finding and floating-point safeguards are all parts of this story.

2 - Lifting nonnegativity over general semialgebraic sets to nonnegativity over simple sets.

Juan Vera

Semidefinite optimization hierarchies are the standard approach to Polynomial Optimization and generalized moment problems. Several authors have proposed hierarchies based on other conic alternatives lately. These alternatives replace the sum of squares with different classes of non-negative polynomials. The convergence of such hierarchies is rooted in Positivstellensatz, which guarantee particular types of non-negative certificates.

We propose a universal approach to derive new Positivstellensatz for general semialgebraic sets from ones developed for simpler sets, such as a box or a simplex. We illustrate the approach by constructing Positivstellensatz over compact semialgebraic sets based on any given cone of non-negative polynomials. Also, we show how to use our results to derive sparse Psatz and to extend them to unbounded semialgebraic sets.

1 - Solving General Assemble-to-Order systems via Component-Based and Product-Based Decomposition Methods

Mohsen Elhafsi, Jianxin Fang, Essia Hamouda

Assemble-to-order (ATO) strategies are widely used in various industries. Despite their popularity, ATO systems remain challenging, both analytically and computationally. We study a general ATO problem modeled as an infinite horizon Markov decision process. In particular, we consider a system with mixed-Erlang distributed component production/leadtimes, and Poisson demand for products. Demand is lost if not immediately satisfied. As the optimal policy of such system is computationally intractable, we develop two heuristic policies based on decomposition methods: component-based and product-based. In order to evaluate the performance of the heuristics, we develop a tight lower bound using an Approximate Linear Programming approach that relies on a judicious choice of basis-functions, for approximating the optimal value function. Our results show that the heuristics perform within only few Average Percentage Deviation (ADP) from the lower bound and even a smaller ADP when compared to systems where the optimal policy could be obtained. Moreover, we show that our component-based decomposition heuristic only scales linearly with the number of components in the ATO system, and therefore is suitable for solving large-scale ATO systems.

2 - Cost-Effective Quality Assurance: Optimizing Inspection Station Placement in Queueing Network Production Systems

Boualem Rabta

This research addresses the optimization of inspection station placement in production systems modeled as queueing networks, where defects may arise at multiple stages. Our proposed optimization model aims to minimize total costs and/or production lead time by determining the optimal number and placement of inspection stations within the network. By strategically positioning inspection stations, we mitigate the risk of defects propagating through the system, enhancing product quality and operational efficiency. We present numerical examples and evaluate various scenarios to identify the most effective configurations. This research contributes to advancing operational efficiency and quality management in complex production systems, offering practical insights for decision-makers in optimizing resource allocation and enhancing overall system performance.

3 - Achieving emergent symmetry in high tech supply chains

Mirjam Meijer, Dennis Schol, Willem van Jaarsveld, Maria Vlasiou, Bert Zwart

For manufacturers of high-tech products, such as aircraft, lithography machines, etc., it is of key importance that all required components are available at the time of assembly. This is a major challenge, as the number of components required for assembling such complex systems is enormous and most of them are sourced at external suppliers. For a supplier, the risk of over-investing in costly capacity is high, while the lost revenue of one missing component is much lower than the value of the manufacturer's end-product. Therefore, each supplier will trade off the cost of investing in additional capacity against the risk of being unable to deliver. Ultimately, the overall delay in delivery of the end-product is determined by the supplier with the largest backlog. To reduce the risk of component shortages, the manufacturer aims to motivate suppliers to invest in excess production capacity, for example by charging a fee for each time unit the supplier delivers past a previously agreed lead time. We model a manufacturing system consisting of a manufacturer and a large number of suppliers, each producing a single component that is required in the manufacturer's assembly process of the end-product. We consider the decentralized optimization problem where each supplier determines their own optimal service rate. We analyze how the contract parameters can be set such that the suppliers choose the service rates that are asymptotically optimal for the supply chain as a whole.

4 - A Mean Value Approach to Continuous Polling Models with Batch Arrivals

Tim Engels

Polling models are classes of queueing models in which a server attends to several queues. By cyclically visiting the queues, the server serves awaiting customers. The analysis of these systems is involved and provides computationally involved results. Therefore, the approximation of these models by their continuous counterparts can be quite helpful. In this talk, we analyze continuous polling models with batch arrivals and deploy a novel mean value analysis to (i) find the average spread of customers and (ii) derive some key performance statistics of polling models; delivery times and batch sojourn times. The resulting approximations are shown to already be quite accurate for polling systems with small numbers of queues.

Chair: Flora Spieksma

1 - An Application to Markov Decision Models in Healthcare Screening

Masayuki Horiguchi

In this talk, we consider the evaluation of periodic screening programme for woman breast cancer and formulate the model as a partially observable Markov decision process (POMDP). We convert a POMDP with finite state, observation state and action spaces to an equivalent completely observable MDP with continuous state and finite action spaces. By this approach, we have an optimal policy from dynamic programming (DP) equation in an equivalent MDP, but we focus on considering the evaluation in several scenarios of periodic screening for participants with silent condition of breast cancer and seeking an answer which programme is better than others for themselves. The aim of our research is, by using the data sets based on cancer registration and estimated parameters of survival rates and other ratios related to screening and diagnoses in Japan, to evaluate the validity of general recommendation with respect to the consideration of human health in scenarios of breast cancer screening programme in POMDP.

2 - Markovian Degradation Modeling of Rails

Steven Harrod, Albert Skovgaard Bisgaard

Rail defects pose a significant threat to railway safety and efficiency. Probabilistic modeling of defect propagation has the potential of improving decision-making for circumvention of dangerous rail degradation.

We propose a continuous-time Markov chain with transition rates regressed on location-dependent covariates to model discretely observed degradation trajectories discovered at the Norwegian rail network. We propose two estimation approaches. The first approach obtains the full data log-likelihood by Monte Carlo simulation of full data defect trajectories, which informs the Expectation-Maximization algorithm. The second approach maximizes the discrete data log-likelihood informed by analytical gradient information.

Both methodologies give rise to fast convergence of model estimates with similar numerical values. Moreover, the estimated coefficients for the covariates are found to be statistically significant and in directional accordance with their physical interpretation. Model checking suggests a robust framework that describes enough variance to satisfactorily account for the structural variability between the rail lines.

We apply the proposed model setting to produce probabilistic forecasts of a defect's growth based on its location in a railway network. The probabilistic setting allows for straightforward scenario generation constituting useful input to decision-making models under uncertainty for maintenance planning.

3 - Learning to Simulate: Generative Metamodeling via Quantile Regression

Qingkai Zhang

Stochastic simulation models, while effective in capturing the dynamics of complex systems, are often too slow to run for real-time decision-making. Metamodeling techniques are widely used to learn the relationship between a summary statistic of the outputs (e.g., the mean or quantile) and the inputs of the simulator, so that it can be used in real time. However, this methodology requires the knowledge of an appropriate summary statistic in advance, making it inflexible for many practical situations. In this paper, we propose a new metamodeling concept, called generative metamodeling, which aims to construct a "fast simulator of the simulator". This technique can generate random outputs substantially faster than the original simulation model, while retaining an approximately equal conditional distribution given the same inputs. Once constructed, a generative metamodel can instantaneously generate a large amount of random outputs as soon as the inputs are specified, thereby facilitating the immediate computation of any summary statistic for real-time decision-making. Furthermore, we propose a new algorithm—quantile-regression-based generative metamodeling (QRGMM)—and study its convergence and rate of convergence. Extensive numerical experiments are conducted to investigate the empirical performance of QRGMM, compare it with other state-of-the-art generative algorithms, and demonstrate its usefulness in practical real-time decision-making.

4 - On the Deviation matrix of an ergodic denumerable Markov process in continuous time with applications

Flora Spieksma

The deviation matrix is a measure of the cumulative deviation from the limiting probabilities and plays an important role in e.g. Markov (decision) processes, perturbed Markov processes, queueing theory, and network centralities. It is well-known that the deviation matrix in the irreducible case exists if and only if the second moment of the return time from a fixed state to itself is finite. We provide a necessary and sufficient condition for the deviation matrix to exist in the form of a system of two nested Lyapunov functions, the equivalent of which has been known for a long time for discrete time Markov chains. However, it has not been realised earlier that finiteness of the deviation matrix implies that the absolute cumulative deviation from the limiting probabilities is finite as well. There is a relatively simple (but not simply proved) argument why this is true. We further present a formula for the deviation matrix in terms of a rank one perturbation of the q -matrix. We will illustrate our results with some applications

Invited session

Chair: [Alexandru Kristaly](#)

1 - Sharp spectral gap estimates for higher-order operators on Cartan-Hadamard manifolds

Csaba Farkas

The goal of this talk is to provide sharp spectral gap estimates for problems involving higher-order operators (including both the clamped and buckling plate problems) on Cartan-Hadamard manifolds. The proofs are symmetrization-free – thus no sharp isoperimetric inequality is needed – based on two general, yet elementary functional inequalities. The spectral gap estimate for clamped plates solves a sharp asymptotic problem from Cheng and Yang [Proc. Amer. Math. Soc., 2011] concerning the behavior of higher-order eigenvalues on hyperbolic spaces, and answers a question raised in Kristály [Adv. Math., 2020] on the validity of such sharp estimates in high-dimensional Cartan-Hadamard manifolds. As a byproduct of the general functional inequalities, various Rellich inequalities are established in the same geometric setting.

2 - Nonlocal critical growth elliptic problems with jumping nonlinearities

Raffaella Servadei

In this talk we deal with some nonlocal critical growth elliptic problem driven by the fractional Laplacian, with particular emphasis on equations in presence of jumping nonlinearities. Using variational and topological methods, we prove the existence of a nontrivial solution for the problem under consideration. These existence results can be seen as the nonlocal counterpart of the ones obtained in the context of the Laplacian equations. In the nonlocal framework the arguments used in the classical setting have to be refined. Indeed the presence of the fractional Laplacian operator gives rise to some additional difficulties, that we are able to overcome proving new regularity results for weak solutions of nonlocal problems, which are of independent interest. This is a joint paper with Giovanni Molica Bisci, Kanishka Perera and Caterina Sportelli (Journal des Mathématiques Pures et Appliquées, 2024).

3 - Solitons of the spacelike mean curvature flow in generalized Robertson-Walker spacetimes

Giovanni Molica Bisci

Our purpose in this talk is to present some results related to the study of solitons of the spacelike mean curvature flow in a generalized Robertson-Walker (GRW) spacetime. Under suitable constraints on the warping function and on the curvatures of the Riemannian fiber, we apply suitable maximum principles in order to obtain nonexistence and uniqueness results concerning these solitons. Applications to standard models of GRW spacetimes, namely, the Einstein-de Sitter spacetime, steady state type spacetimes, de Sitter and anti de Sitter spaces, are given. Furthermore, we establish new Calabi-Bernstein type results related to entire spacelike mean curvature flow graphs constructed over the Riemannian fiber of the ambient spacetime (Joint work with Márcio Batista, Henrique F. de Lima and Wallace F. Gomes New York J. Math. 29 (2023) 554-579).

Optimization in Quantum Information

Stream: Quantum Computing Optimization
Invited session

Chair: Gereon Koßmann

1 - Optimization of the Relative Entropy under linear constraints via semidefinite programming

Rene Schwonnek

Optimizing the quantum relative entropy under linear constraints is a central problem in Quantum Key Distribution (QKD) and other fields of (Quantum) Shannon theory. In particular providing provable lower and upper bounds is a highly relevant task. We provide a practical and resource efficient method for this problem. At the core of our work stands a recently described, and pleasingly elegant, integral representation of the quantum relative entropy, which we employ in order to formulate the problem of reliably bounding it as an iteration of semi definite programs (SDP). In contrast to existing techniques, our method comes with a provable convergence guarantee of quadratic order, whilst staying resource efficient with the matrix dimension of the underlying SDPs. We furthermore can provide an estimate for the gap to the optimum at each stage of the iteration. Combining this with some clever heuristics for the iteration, we find that convergence can in practice be actually achieved much faster than theoretically guaranteed.

2 - From barren plateaus through fertile valleys: Conic extensions of parameterised quantum circuits

Timo Ziegler, Gereon Koßmann

Unconstrained optimization problems such as integer linear programs can be relaxed to the task of finding the ground state of a physical system described by a quantum state. In the realm of quantum devices having comparably low numbers in qubits prone to noise, quantum circuits consisting of a sequence of parameterised unitary gates controlled by classical optimization methods are the prevalent technique of near-term quantum algorithms. However, the omnipresent phenomenon of barren plateaus - parameter regions with vanishing gradients - sets a persistent hurdle that drastically diminishes their success in practice. In this work, we introduce an approach -based on non-unitary operations - that favours jumps out of a barren plateau into a fertile valley. These operations are constructed from conic extensions of parameterised unitary quantum circuits, relying on mid-circuit measurements and a small ancilla system. We further reduce the problem of finding optimal jump directions to a low-dimensional generalised eigenvalue problem. As a proof of concept we incorporate jumps within state-of-the-art implementations of the Quantum Approximate Optimisation Algorithm (QAOA) - a prominent descendant of the class of variational

quantum algorithms. We demonstrate the extensions' effectiveness on QAOA through extensive simulations, showcasing robustness against barren plateaus and highly improved sampling probabilities of optimal solutions.

3 - Efficient Prediction of Quantum Ground State Properties via Classical Machine Learning with Geometric Locality

Viet Tran

An fundamental optimization problem in quantum physics is finding the ground state of quantum many-body systems. Addressing this challenge, our presentation highlights numerical experiments that utilize a classical machine learning (ML) algorithm leveraging a geometric locality inductive bias to efficiently predict ground state properties. Our experiments on systems up to 45 qubits illustrate the model's ability to accurately predict ground state properties with only $O(\log(n))$ instances from similar Hamiltonians, demonstrating a substantial efficiency improvement over previous state of the art methods with polynomial sample complexity. These findings validate theoretical improvements on the sample complexity bound for geometrically informed ML algorithms.

Additionally, if time allows, we will delve into preliminary findings from ongoing research in the domain of shadow tomography facilitated by diffusion models, exploring their potential to further advance our understanding of quantum systems.

4 - de-Finetti Methods for Channel Coding Theory

Gereon Koßmann

Maximizing the channel fidelity is a major problem in quantum information theory. Many methods have been developed for inner points and for some error models exact codes are available. In general, however, one would be interested in certificates, i.e. outer bounds. In this talk, we will present a method for generating outer points and a hierarchy that also allows for inner points. The talk is based on the standard quantum de-Finetti hierarchy for problems with linear constraints (arxiv: 1506.08810). Starting there, we are able to prove the existence of a sequence of inner points, which have similar error bounds as the outer bounds. This result yields that at least theoretically certification of actual error correcting codes becomes possible.

Chair: Harit Joshi

1 - Modelling the choice between labour and leisure and short-run profit maximization of the monopsonist - bilevel programming approach

Mira Krpan, Zrinka Lukac, Vedran Kojić

This paper models the labour-leisure choice problem with Cobb-Douglas preferences and the short-run profit maximization problem of a monopsonist with Cobb-Douglas technology as a bilevel programming problem. The solution of the problem is discussed and the results are enriched by economic interpretations and numerical examples.

2 - Attaining Approximate Stability in Large Two-Sided Matching Markets

Chun Wang, Jie Gao, Shixuan Hou

A two-sided market is an economic platform that enables direct interactions between two distinct customer groups, providing each other with network benefits. Matching is the fundamental function that ensures the viability and service quality of such markets. While the Gale-Shapley algorithm and its variants can be used to compute stable matchings for two-sided markets effectively, these methods typically require participants to rank all potential partners, posing a significant cognitive burden to them and rendering it impractical for large-scale markets involving hundreds or thousands of options on each side. This paper presents an efficient framework for computing approximately stable matchings in large-scale and dynamic market settings. Instead of explicitly eliciting preferences, we employ probabilistic choice behavior models trained on participants' historical interaction data with the platform. These models serve as incremental preference elicitation tools, which adapt themselves through continuous machine learning techniques. Additionally, we devise procedures for robust matching in the presence of probabilistic and evolving preference information provided by the behavior models. We conduct a simulation study to experimentally quantify the impact of enforcing approximate stability within a dynamic crowd-sourced delivery services setting, utilizing preference survey data collected from crowd-sourced drivers.

3 - Platform coordination in ride-hailing through matching and pricing

Harit Joshi, Saral Mukherjee

Ride-hailing has evolved from the decentralized model in which taxis operate independently to the centralized model with on-demand matching of customer travel requests with the available drivers. The existence of a coordinator is a difference between the decentralized model of hailing taxis and the centralized matching in ride-hailing platforms. More research needs to be conducted to quantify the differentiated value provided by the platform and how this value changes in different contexts. In this paper, we quantify the value of coordination through matching in ride-hailing platforms by comparing differences in performance metrics between centralized and decentralized models. The performance metrics include supply-side metrics like driver utilization, demand-side metrics like customer search time, and platform-side metrics like the number of unmatched customers. Using an agent-based model, we show that the value of coordination is different for the two sides of the platform. We explore how the value of coordination changes with variations in (i) demand and supply characteristics like the spatiotemporal distribution of demand, (ii) driver characteristics like knowledge of high-demand zones, (iii) customer characteristics like patience levels, and (iv) network characteristics like topography. Our analysis offers insights to the platforms in understanding the role of demand, supply, behavioral, and network characteristics in the value generated through their operations.

Decision problems are often characterized by complex criteria dependencies, which can hamper the development of an efficient and theoretically sound multicriteria decision aid model. These criteria interactions have the form of either redundancy or synergistic effect and require arduous and demanding preference statements for their quantification. In this paper, criteria interactions in decision models are addressed with the proposition of an MCDA framework, coupling the preference elicitation protocol of the method of cards and the Choquet integral preference model, which is approached as an importance index. An interactive robustness control algorithm ensures the concurrent acquisition of a stable decision model and satisfactory evaluation results. Robustness is assessed with a portfolio of robustness indicators, spanning from the variability of the preference parameters to the reduction of the model's feasible space and rank acceptability indices. At the algorithm's core, a heuristic module generates pairwise elicitation questions and selects those delivering the highest expected information gain. The whole framework is stress-tested with a small-scale decision problem, where three versions of the heuristics are automatically applied, with the machine randomly answering the questions. Subsequently, the same problem is approached with the involvement of a real decision-maker, to appraise the required cognitive effort and receive valuable feedback.

2 - ScoreBin: Scoring Alternatives by Fusing a Crisp Outranking Relation and Indirect Decision Maker's Judgments

Krzysztof Martyn, Magdalena Martyn, Milosz Kadzinski

We introduce a suite of multiple criteria methods that fuse two sources of information. On the one hand, we exploit a crisp outranking relation in the set of alternatives. For each option, we analyze the outranked and outranking alternatives to compute its strength, weakness, and comprehensive quality. We propose four variants that differ in weights assigned to outranking or being outranked by particular alternatives and how to quantify the difficulty or easiness of instantiating such relations. On the other hand, we consider the Decision Makers' holistic judgments, indicating subsets of alternatives deemed as comprehensively strong or weak. We apply the proposed methods to a case study concerning the performance of technological parks in Poland. We also compare the results obtained with the novel approaches with the state-of-the-art ELECTRE methods in an extensive experiment involving simulated decision problems.

3 - Attaining Robust Performance Targets in Data Envelopment Analysis with Application to Efficiency Evaluation of Airports

Dariusz Grynia, Milosz Kadzinski

We consider a ratio-based efficiency analysis in view of achieving performance targets by Decision Making Units. The targets refer to the efficiency scores or ranks and the truth of pairwise preference relations. These outcomes can be instantiated for at least one or all feasible weights associated with inputs and outputs. We discuss Multiple Objective Optimization problems that minimize the required reductions of consumed resources or increases of produced results needed to reach the pre-defined aims. The proposed models offer great flexibility to the Decision Maker, who can indicate which factors should be modified and to which extent. The evolutionary optimization algorithm computes a set of solutions that exhibit the trade-offs between expected modifications of various factors. They can serve as the basis for interactively selecting the most preferred solution to be implemented in practice. The use of the proposed framework is illustrated in the problem of analyzing the efficiency of Polish airports.

4 - Robust Additive Value-Based Efficiency Analysis with a Hierarchical Structure of Inputs and Outputs

Anna Labijak-Kowalska, Milosz Kadzinski

We introduce a novel methodological framework based on additive value-based efficiency analysis. It considers inputs and outputs organized in a hierarchical structure. Such an approach allows us to decompose the problem into manageable pieces and determine the analyzed units' strengths and weaknesses. We provide robust outcomes by analyzing all feasible weight vectors at different hierarchy levels. The

Emerging Trends in Decision Analysis

Stream: Decision Support Systems

Invited session

Chair: Pavlos Delias

1 - Information/Throughput Tradeoff Mitigation in Automated Sorting

Magnus Berg Ladefoged, Andreas Larsen

Conveyor belts are often used in conjunction with robotic arms for automated manufacturing processes. For moving and packing, the robotic arms automatically pick the items on the conveyor and place them in containers. This is however essentially a TSP, and efficiency thus requires a sophisticated control scheme. Increasing the look-ahead is a way to introduce more information to the system, however this might lead to a decreased throughput as the system waits for the perfect item and sub-par items run off or are recycled into the system. A key factor will be intelligently incorporating the look-ahead information in the constraints of the optimization problem, to limit the negative impact on throughput of the system while maintaining the benefits of the larger solution space. This paper proposes to extend the objective function to include the look-ahead and incorporating the associated time penalty in the problem constraints using a temporal-distance scoring metric. Furthermore, the decision cycle will be included in the problem formulation as it directly relates to the problems' temporal nature.

2 - Application of Predictive Analytics in Assessing Student Performance: A Case Study in a Computer Supported Collaborative Learning Environment

Yannis Psaromiligkos, Athanasios Spyridakos, Natasa Themeli, Theodoros Anagnostopoulos, Christos Kytagiias, Dimitris Papakyriakopoulos

In contemporary collaborative learning environments, characterized by intricate activities and numerous stakeholder interactions, there's a pressing need to gather insights from diverse sources to attain a comprehensive understanding of learning dynamics and students' behaviours. While Learning Management Systems serve as the cornerstone of these environments, their data analysis capabilities are often limited to basic metrics such as visit frequency, completion rates, and score statistics. Consequently, there's a high demand for specialized tools to support instructional designers. Decision support in the form of Learning Analytics, rooted in the domain of business intelligence, has emerged as a forefront area of research in technology-enhanced learning. In this paper, we present the application of predictive analytics within a multi-criteria dataset structure to categorize students based on their performance in collaborative activities. Our approach was deployed in a real-world scenario involving two cohorts of an undergraduate course conducted entirely online due to the pandemic. The first cohort comprised 337 students organized into 81 groups, while the second cohort consisted of 341 students divided into 76 groups. We applied various machine learning algorithms to determine the algorithm yielding optimal performance.

3 - Modelling Dependencies Between Criteria with Fuzzy Functional Dependence

Frantisek Zapletal

Evaluation of the importance of criteria using weights is usually an integral part of solving multi-criteria decision-making (MCDM) problems. MCDM methods often require independent criteria, but this may not be true for real problems. Significant dependence then leads to either a reduction or a strengthening of importance. There are several approaches that can reflect the dependency between criteria, e.g., CRITIC method or the methods based on the Choquet integral. Existing approaches, however, suffer from drawbacks. They are based on the correlation which does not reflect the direction of dependence or expert evaluations. This contribution focuses on the application of the fuzzy functional dependencies (FFD) to reflect the dependencies between criteria in their weights. The model is tested using several numerical examples.

4 - Advancing Business Process Evaluation: The Value of Integrating Process Mining and Propensity Score Analysis

Pavlos Delias, Giannoula Florou, Nikolaos Mittas

Ensuring the efficacy of business process interventions is essential for informed decision-making and sustained improvements. This study focuses on a pragmatic approach that integrates process mining and the strengths of propensity score analysis to enhance precision and reliability in evaluating business process interventions. Drawing from our prior work, we present a practical methodology tailored for organizations seeking an effective solution. We aim to construct a framework that utilizes both event logs and observed characteristics to address confounding factors, thereby enhancing the validity of conclusions in observational studies. Our work is complemented by a prototype tool designed to assist practitioners in selecting appropriate weighting methods, evaluating group balance, and assessing covariate balance. Through an applied case study on a simulated claims management process dataset, we illustrate how these techniques synergize to measure and enhance business process effectiveness and efficiency. This study not only underscores the integration of process mining, business process management, and causal inference but also scrutinizes the inherent limitations and challenges. By providing a comprehensive view, our goal is to offer organizations actionable insights, implementation guidance, and an understanding of how this synergy can advance business process evaluation.

The Quest For The Right OR Professionals

Stream: Making an Impact

Invited session

Chair: Sander Van Aken

1 - The Quest for the Right OR Professionals - a Hiring Perspective (90' panel discussion)

Making An Impact, Sander Van Aken, Michael Lindahl, Susanne Heipcke, Henning Blunck

In this 90' panel session, recruiters of OR professionals, data scientists or analytics people will discuss and compare how they go about it, and address burning questions relevant to both those recruiting professionals, as well as those looking to secure a new industry position.

How do companies and teams come to define the profile to hire, crafting the job ad? What skillset and traits do you look for, and how do you define that? How do you design a hiring process covering those aspects, and what are the challenges and best practices for the recruiting team themselves? What advice would the hiring team give their counterparts.

Join us to learn about each other's challenges, best-practices, and ask your own questions during a Q&A.

For the latest details of speakers, please see the Making an Impact page on the main conference website <https://euro2024cph.dk/programme/making-an-impact-2024>

1 - Elaboration of a Multi-Dimensional Decision Support System for Strategic Energy Planning: Application to Production and Trade of Green Hydrogen

Maria Cristina Pinto, Maria Gaeta, Piero Boccardo, Stefano Corgnati

Even if energy-based, the transition towards decarbonization is a multi-dimensional process evolving over time and space and related to the broader social, techno-economic, environmental, and geopolitical aspects. While facing the uptake of new technologies or strategies in the energy system framework, it is important to address this complexity, to support policymakers in strategic planning. In this regard, the work aims to elaborate a structured science-based decision-making approach, through the exploitation of different instruments and tools, i.e. multi-criteria decision methods, spatial analyses, modelling of energy scenarios. A three-step procedure is developed, based on the evaluation of three concepts: (i) predisposition, through the application of a Multi-criteria Analysis; (ii) multi-dimensional suitability, exploiting a Multi-criteria Spatial Decision Support System; (iii) competitiveness, by modelling energy scenarios. Elaborated to be scalable and replicable for different strategic energy planning processes, the approach is exploited to assess if and how (i) North African countries are predisposed to green hydrogen production, (ii) North African areas are suitable for green hydrogen production, (iii) the trade to Europe can be competitive in the long-term. This approach allows to investigate the multi-dimensional patterns of the transition and its key players like hydrogen, through heterogeneous instruments able to express the heterogeneity of the process.

2 - An ESG Indicators Framework for Construction and Real Estate Companies

Daniela Santana Tovar, Sara Torabi, Patrizia Lombardi

The construction industry is widely recognized as one of the most environmentally sensitive sectors, having a significant impact when adopting sustainable development practices. Environmental, Social and Governance (ESG) stand as the three primary pillars of a company's sustainability performance, which contrast with the pillars defining sustainable development. Notably, ESG play a critical role in evaluating company performance by revealing inherent risks. Despite the widespread use of indicators, there exists a notable gap in those specifically oriented to assess company performance within the construction industry. However, research in how to achieve a standard framework to evaluate and report ESG performance in companies are still very limited. This paper aims to develop a framework of indicators relevant to the construction industry within a European context, serving as a tool to measure ESG performance. The methodology consists of the characterization of a set of indicators drawn from established protocols for assessing and reporting ESG criteria such as GRI and GRESB. Through a selection process, 169 indicators categorized into

environmental, social and governance, enables construction companies to assess comprehensively ESG performance. Future research opportunities include in the definition of a methodology to identify material indicators for each company and the definition of benchmarks in the contextualization of the framework.

3 - Territorial rebalancing in an axiological perspective. An Reaction Capacity Index of Sicily's inner areas

Maria Rosa Trovato, Ludovica Nasca

The marginalisation of the inner areas due to increased social, material, economic, infrastructural vulnerability is a phenomenon that afflicts many countries today and is growing rapidly. In recent years, specific policies, measures, and funding have been proposed aimed at counteracting this phenomenon. To date, despite the increased awareness of the issue of marginal areas and the growing concern about the progressive decline and abandonment of large areas of territory, current policies are slow to produce the expected effects. The heritage of weak areas, if properly integrated, can become a resource, an opportunity for the whole territorial system. Decision-makers engaged in the prospect of the territorial rebalancing will have to be supported in identifying the residual values of these marginal areas, to recognise where and how it can be significantly emphasised in the prospect of an integrated long-run redevelopment process. The research, according to a multicriteria-based axiological approach, proposes the construction of a Reaction Capacity Index (RCI) of the internal areas of Sicily. The estimation and representation in QGIS of the RCI provides an overall framework based on which decision makers can identify specific policies and actions aimed at favouring a territorial rebalancing. The methodological approach for estimating the RCI index that provides an overall measure of territorial capital endowment is developed based on the Multi-attribute Value Theory (MAVT).

4 - Spatial multidimensional evaluation of impacts generated by the Porta Nuova district in Milan (Italy): a purpose perspective.

Alessandra Oppio, Marta DellOvo, Danny Casprini

An urban regeneration project brings the creation of tangible and intangible effects that arise from the design choices adopted, as well as from the sustainability goals identified. The tangible effects of the intervention are traditionally intercepted by economic evaluation models and allow design choices to maximize the developer's economic return. In addition, intangible effects are generated, such as, the impact on the quality of life, environmental impacts, and the social and cultural vibrancy of the area. Defining, and even more quantifying, the intangible effect of a project is complex, requiring effort in analyzing the intentionality and additionality that lead to the creation of added value for the area in which the project is located and for the community that benefits from it. The objective of the study is to identify and measure the impacts and the social additional value generated by the urban regeneration of the Porta Nuova district while considering the effects it has triggered on neighboring districts in the city of Milan and at larger scale. A multimethodological approach, based on Stakeholders' Analysis, Multiple Criteria Spatial Decision Support Systems (MC-SDSS) and Community Impact Evaluation (CIE) has been developed to identify the purpose and the dimensions impacted by the urban project on the different stakeholders categories. The final result highlights the spatial distribution and the intensity of impacts from a purpose perspective.

1 - Croatian Universities Under the Microscope: Who Leads, Who Lags, and Why?

Katerina Fotova Čiković, Damira Keček, Violeta Cvetkoska

In an era propelled by knowledge, our study pioneers a cutting-edge evaluation of teaching and research efficiency in Croatian universities, employing a sophisticated blend of AHP, DEA, and regression analysis. Our extensive literature review from the Scopus database, spanning scholarly discourse from inception to 2023, unveiled crucial focuses: teaching and research efficiency, and their convergence. Distilling insights, we constructed a refined framework for inputs and outputs, utilizing AHP, and engaging diverse respondents—Ministry of Education, university rectors, and higher education policy advisors—in a structured comparison. They assigned relative importance to input and output hierarchies for teaching and research efficiency. The highest-ranked factors, determined by AHP, shaped the DEA analysis, revealing the efficiency frontier and enabling targeted improvement strategies for universities based on quantified efficiency scores. In parallel, our study delves into the assessment of managerial ability within universities, a pivotal yet often overlooked aspect. Adopting methodologies proposed by Demerjian and Lev (2021) and Banker and Park (2021), we measure the efficacy of managerial decision-making in steering institutions toward relative teaching and research efficiency. By identifying determinants of managerial ability, our analysis contributes insights into the leadership dynamics shaping the overall efficiency of Croatian universities.

2 - Evaluation of the efficiency of research outputs of Korean private universities: a two-stage network DEA approach

Mehdi Shamohammadi

The production and assessment of research outputs are pivotal aspects of the university knowledge generation process, influencing spin-offs and collaborations arising from industry-university research endeavors. While numerous studies have utilized research outputs to gauge university performance, many have primarily concentrated on quantitative variables such as the sheer number of publications and patents. This emphasis on quantitative indicators alone may lead to an over-estimation and bias in assessing research performance in specific instances. Recognizing this limitation, our study aims to address this gap by employing a two-stage network data envelopment analysis (DEA). In addition to quantitative variables, our focus extends to incorporating quality attributes like publication and patent citations alongside the number of research projects. Our dataset spans 57 research-active South Korean private universities from 2010 to 2019. Empirical findings reveal that integrating quality attributes into an appropriate production model enhances the accuracy and reliability of efficiency measurement results. Furthermore, the use of the two-stage network DEA allows for a nuanced observation of the disparity between the quantity and quality stages of university research outputs, presenting a valuable advancement beyond traditional black-box DEA models.

3 - A generalized composition approach in Network Data Envelopment Analysis for complex structures: An application to higher education institutions in Poland

Dimitrios-Georgios Sotiros, Julia Nasiadka, Gregory Koronakos, Dimitris Despotis

Network Data Envelopment Analysis (NDEA) is an extension of Data Envelopment Analysis (DEA) that takes into consideration the internal structure of Decision Making Units (DMUs) in the efficiency assessment. In NDEA, every DMU is conceived as a network of several sub-processes arranged into a series, parallel or mix of series and parallel (complex) structures. In the literature, most of the studies focus on series structures while the drawbacks of the methods developed for the efficiency assessment of parallel structures are neglected. In this paper, we discuss the pitfalls of the most established NDEA method for parallel structures, and we develop a new method to treat these issues. Our method relies on Multi-Objective Programming (MOP) techniques and can be generalized to any type of internal structure. We compare the introduced method with other prominent methods in the literature highlighting the differences and the advantages of the proposed method. Finally, we employ this method to evaluate the teaching and research efficiency of Polish higher education institutions.

Chair: *Elisabeth Finhold*

1 - Optimization of Blister Package Design in Pharmaceutical Industry

Seray Çakırgil, Eda Yücel

This study focuses on enhancing blister packaging operations at a Turkish pharmaceutical company to improve efficiency, reduce costs, ensure regulatory compliance, and contribute to reducing carbon emissions. Blister design significantly influences decisions regarding production, logistics, and investments. While existing research typically addresses challenges after selecting packaging materials and designs, we propose a novel mixed-integer mathematical model to address packaging design, machinery investment, and production planning simultaneously. However, solving this complex problem is computationally challenging. Therefore, we introduce a solution method using a constructive approach and Adaptive Large Neighborhood Search (ALNS). Computational experiments on realistic datasets demonstrate that our proposed method effectively optimizes blister packaging and production planning for various product quantities and time periods. Additionally, our work supports the industry's sustainability goals by promoting eco-friendly packaging practices.

2 - Integrated optimisation for aluminium rolling

Georgios Zois, Ioannis Avgerinos, Apostolos Besis, Yiannis Mourtos, Athanasios Psarros, Stavros Vatikiotis

This work focuses on the aluminium production scheduling problem of a leading European Copper and Aluminium industry. The problem forms an interesting variant of flexible flow-shop scheduling consisting of two successive stages, the preheating and the hot rolling of aluminium slabs i.e.: A set of slabs arrives over time and (in the preheating stage) is assigned to a set of parallel furnaces. Once preheating is completed, each slab is unloaded and immediately transferred to a hot rolling mill. Each furnace operates in a FIFO manner under slabs' eligibilities and capacity constraints, while the hot rolling mill can handle a single slab every time instant, under predefined quality conditions regarding the minimum and maximum number of slabs per production cycle. Each slab is accompanied with preheating and rolling times and is subject to quality restrictions determined by the sequence of slabs in the same production cycle. Slabs also require specific preheating operations and can only be preheated with slabs of compatible operations in the same furnace. We propose an integrated optimisation framework, comprised by an exact method for each production cycle, which combines a MILP and CP formulation for both stages, and a sequential heuristic approach for planning over multiple cycles. We provide experimentation on real instances, showing the versatility of our approach in terms of supporting different planning approaches thus maximising quality of production and machines usage

3 - An Optimization Approach for Controlling Material Flow in a Production Network on a Tactical Level: A Case Study

Elisabeth Finhold, Heiner Ackermann, Till Heller, Felix Höhne

In this talk, we show how we tackle a production planning challenge arising in the real-world application of rubber flooring production. Here, the last of the four major production steps is hard to plan well in advance, due to a large product variety, hard-to-formalize context-dependent rules, sometimes insufficient material supply and unforeseeable events such as staff shortages or machine failures. We developed

a tactical planning approach in which we compute a rough quantity-based production schedule for the four major production steps by solving a linear optimization problem. This schedule adapts to the changing production environment and state of production seamlessly and has two main functions: Firstly, it is used to monitor the flow of material through production to proactively take action if a discrepancy is observed. Secondly, the model is setup in a way such that satisfactory operational schedules for the respective production steps can be derived easily from a well-balanced rough schedule.

The approach was integrated into the company's production planning software. After a one-year test phase in which the model was further customized to this specific production setting, the resulting schedule is now used as the main decision-making tool and process control system by several departments.

4 - A Generalized MILP Model based Co-Clustering Approach: An Application in Cellular Manufacturing

Rahul Prasad, Rajendran C

Efficient machine-part cell formation is crucial for modern manufacturing systems, ensuring high throughput, reduced setup times, and increased flexibility. This paper introduces a novel 2-phase MILP-based Co-clustering model tailored for optimal cell formation in manufacturing systems. Addressing both binary and ratio (workload) input datasets, the model introduces the noble similarity coefficient yielding better results. The objective is to provide an efficient and versatile solution, with a particular emphasis on minimizing inter-cell workloads and reducing idle time within the cells. Unlike probabilistic methods, our model guarantees a deterministic, globally optimal grouping of machines and parts using a mathematical model. The model is successfully applied to over 50 benchmark datasets of binary and workload drawn from Cellular Manufacturing Systems. The model demonstrates superior grouping efficacy and lower time complexity compared to existing methods. Furthermore, a streamlined heuristic follows the mathematical model, enabling efficient machine or part reallocation, further improving the model's efficiency.

Invited session

Chair: Rina Mary Mazza

1 - Simulation-based Optimization for Integrating Storage Location Assignment and Manual Order Picking in Warehousing

Rina Mary Mazza, Jean-François Cordeau, Pasquale Legato

We propose a simulation-based optimization (SO) framework that integrates a novel mathematical formulation for the storage location assignment problem (SLAP) featuring vertical replenishment and a simulation-guided heuristic for manual order picking. Due to the highly-combinatorial nature of the problem, to solve realistic instances, we design a customized iterated local search (ILS) metaheuristic. Specifically, it determines the "top m" promising moves at each iteration of the ILS and then evaluates the corresponding solutions by discrete-event simulation. This allows measuring the impact of location assignments on warehouse productivity, while also accounting for mutual interferences and waiting phenomena arising during the operations carried out by multiple order pickers. The solution bearing the best (estimated) throughput maximization-based objective function of the order picking process is used to update the global optimum. Hence, simulation guides the search and change of the current feasible SLAP solution. Numerical results are presented for a real distribution center under a picker-to-products rack system following an S-shape policy with a skip-and-go rule to deal with lacking items. After a proper

tuning of the ILS parameters and once the ILS has assigned the higher-rotating items as close as possible to the loading gate, the SO framework allows to achieve significant improvements on warehouse productivity.

2 - Storage assignment policies for retail warehouses processing store-specific shipment buildups

Julian Baals, Nils Boysen, Simon Emde, Felix Weidinger

Shop-floor space in urban areas is scarce and expensive. To avoid a time-consuming zigzag movement when replenishing densely arranged shelves, store-specific shipment buildups (SSSBs) mirror the store layout in the packing pattern of the carriers (e.g., roll cages) on which merchandise arrives in brick-and-mortar sales outlets. If a carrier is pre-sorted according to the layout of its designated store, then the sales personnel can follow a clear route through the store while replenishing the shelves. The time savings in the stores come at the price of additional effort in the retail warehouses having to assemble SSSBs, however. If picker-to-parts order picking is applied to assemble SSSBs, then it is the order pickers who must zigzag through the warehouse. In this paper, we develop and test the performance of novel storage location assignment policies that consider order frequencies and store layouts when deciding on the storage positions of stock keeping units (SKUs) on the shelves of a picker-to-parts warehouse. We evaluate these novel policies both with the theoretical optimum if perfect information were available and with traditional SLA policies merely based on order frequencies. These computational tests show that our novel policies can greatly reduce the picking effort during the assembly of SSSBs in picker-to-parts warehouses.

3 - Swarm or System-directed? Analysis of Human-Robot Matching Policies in Collaborative Order Pick Systems

Mahdi Ghorashi Khalilabadi, Debjit Roy, René de Koster

Autonomous Mobile Robots (AMRs) collaborate with humans in order-picking and can increase order-picking efficiency by reducing walking. AMRs can operate under two policies: Swarm or System-Directed. This study models the Swarm policy using a closed queuing model to determine system throughput capacity. The queuing model incorporates AMR-picker matching via a synchronization station. We derive closed-form expressions for network steady states and use these to calculate order throughput. The impact of various factors on overall system performance is analyzed such as order profiles, matching policies (closest or random), AMR and picker speeds, warehouse size, item assignment methods, and AMR-to-picker ratios. Furthermore, we compare the order throughput of the swarm with the system-directed policy to ascertain superior performance under different circumstances. Results indicate that the swarm policy generally outperforms, particularly at higher AMR-to-picker speed ratios. However, its effectiveness diminishes with larger order sizes and lower AMR-to-picker ratios. Overall, the study provides insights into optimizing e-commerce warehouse operations through effective decision-making in swarm collaboration, aiming to enhance productivity and efficiency in order fulfillment.

4 - Direct Dispatch and Order Fulfillment Models in Retail Supply Chains

Narayan Rangaraj, Geetha Bhargavi Katikala, Tilakraj Singh

We explore the potential of implementing a dual supply chain system to replace a conventional one driven by a typical large Consumer Packaged Goods (CPG) firm. The dual supply chain would deliver finished products both through distribution centers and through direct dispatch to retailers. Demand information and the cost structure from the company's production facilities and existing supply chain were analyzed to build and validate a model for the dual supply chain within planning constraints.

The objective is to reduce operating costs by using the opportunity for direct dispatch, considering network restrictions. Direct dispatch possibilities were identified, based on customer segmentation, across time and across locations. Aggregation is possible both temporally (combining orders over multiple days, subject to inventory and service level constraints) and spatially (combining orders at nearby locations, subject to vehicle movement constraints). Heuristic approaches and exact optimization models were applied. The detailed example considers 243 customers (retailers) of a plant of the CPG firm. Of these, 24 feasible direct dispatch customers were identified, yielding a Direct

Dispatch Opportunity Rate of 14.41% for the plant resulting in cost reduction. The model is extendable to multi factory situations, and leads to interesting modeling issues in fixed cost allocation and consideration of different aspects of service in retail supply chains.

Portfolio risk management

Stream: Risk management in finance

Invited session

Chair: *David Neděla*

1 - Decision-making of Liquor Retailer based on Modified Portfolio Theory

Xiaotong Sang

A complete retail supply chain consists of suppliers, retailers, and customers. Retailers generally bear greater risks, such as how to choose suppliers and how many suppliers to choose. Portfolio theory seeks to optimize portfolio structure and maximize returns. This project is based on the perspective of the retailer and applies the Portfolio Theory to the decision-making of the retailer. The aim of this project is to select an order structure and financing method for the retailer that match the expected revenue based on mean-variance theory. For this purpose, this project collected data on a liquor retailer, basically classifying suppliers into two categories, which include five products, and finding out how the retailer should build orders to achieve the maximum expected revenue. In addition, considering the situation that the retailer has inventories and has difficulty financing, this project uses the classical newsvendor model to optimize the management of the inventory of the retailer and gives financing suggestions based on the results. Conclusively, find out the supplier portfolio under the modified portfolio theory and give private suggestions.

2 - Based on the applicability of the KMV model in Chinese commercial banks

Shikai Gao

The project selected ten listed commercial banks as the research object, and based on the financial data of the sample banks in 2022, the KMV model was used to measure the credit risk of the banks. The aim of this project will be to test the applicability of the KMV model in the measurement of the credit risk of commercial banks in China. First, the volatility of stock prices, the value of bank assets, and their volatility are calculated according to the Black-Scholes option pricing model. Then the KMV model is applied to calculate the default distance of each commercial bank. Finally, the expected default frequency is obtained. The expected default frequency obtained is compared with the standard range of Standard & Poor's and Moody's ratings. The final results show that the expected default frequency of the banks calculated using the KMV model generally matches the credit ratings of the banks by the credit rating agencies. The higher the expected default frequency, the lower the credit rating. Lastly, relevant suggestions are made for commercial banks to improve credit quality and strengthen the level of supervision.

3 - Mean-trend risk portfolio selection with non-dominated sorting asset preselection

David Neděla, Sergio Ortobelli Lozza, Tomáš Tichý

By monitoring the financial markets, we can discover a huge number of potential assets to be invested in. It is very complicated and time-consuming to analyze all assets and then use all of them in optimization according to the preferred portfolio strategy. For this reason, it is potentially useful for portfolio managers to focus on a specific sample of assets identified by the filtering process. This paper proposes an efficient approach for asset preselection based on multidimensional

non-dominated sorting of selected asset statistics. In contrast to previous research, we designed an innovative application on statistics obtained from approximated return series using nonparametric regression and principal component analysis (PCA). Additionally, we study its impact on mean-variance and recently proposed complex mean-trend risk large-scale portfolio selection strategies. In particular, this process examines the efficient frontier of portfolios on the basis of differing return and risk perspectives. In the empirical part applied to the US stock market data, we present an ex-post and ex-ante analysis with results for 40 portfolio strategies. The results obtained strongly indicate that for most risk-averse investors, the mean-trend risk strategies with the preselection outperform the same strategies without the preselection, as well as the mean-variance strategies.

4 - Dynamic Investment Model for Pension Funds: Maximizing Mean-Risk Performance with SD constraints

Audrius Kabasinskas, Milos Kopa, Kristina Sutiene, Sebastiano Vitali

This study introduces a dynamic investment model for pension fund managers, aiming to optimize mean-risk performance over a 21-year horizon. The model reacts to past asset returns, with annual rebalancing, and seeks to outperform benchmarks using second-order stochastic dominance. We explore the possibility of identifying a universally preferred dynamic strategy for all risk-averse investors and examine its characteristics compared to benchmarks. The model maximizes mean-0.5*CVaR with stochastic dominance constraints, utilizing historical extraction for future returns. Benchmarks follow a 1/N portfolio strategy, evolving asset allocations over time according to pension fund regulations. Results for the benchmark show an average terminal wealth of 2.7 EUR after 21 years, with a 5% probability of falling below 1 EUR. The optimal strategy, without ESG restrictions, outperforms the benchmark, exhibiting higher cash and bond investments, resulting in an expected terminal wealth of 6 EUR. When considering only ESG attractive assets, the optimal strategy is less profitable (expected terminal wealth of 3.6 EUR), yet it outperforms the benchmark in second-order stochastic dominance. The optimal strategy demonstrates sensitivity to asset bounds and ESG considerations, emphasizing the importance of strategic asset selection over risk aversion parameters. The project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-21-32.

Scheduling and Routing Problems

Stream: Combinatorial Optimization

Invited session

Chair: *Léa Ricard*

Chair: *Fabian Torres*

1 - A Two-Echelon Vehicle Routing Problem with Mobile Satellites and Multiple Commodities

Aria Dahimi, Virginie Lurkin, Mehrdad Mohammadi, Tom van Woensel

The surge in last-mile delivery demands, driven by the growth of e-commerce, poses intricate challenges in meeting tight schedules, navigating congested urban areas, and addressing environmental concerns. In this study we introduce an approach to address a part of last-mile delivery challenges by integrating a mobile two-echelon strategy. We extend traditional two-echelon systems to consider multiple depots, multiple commodities, and flexible meeting points (mobile satellites). To solve this complex problem, we propose a mixed-integer linear programming (MILP) model and a math-heuristic algorithm, SALNS, combining large neighborhood search (LNS), LP scheduling, and a novel schedule approximation method. Comprehensive experiments demonstrate the algorithm's efficiency, achieving identical or superior results to exact benchmarks while running, on average, nine times

faster. Notably, the algorithm robustly generates feasible solutions for medium and large instances in practical times. Furthermore, sensitivity analyses reveal the critical roles of fuel, wage, and time-window parameters in shaping delivery strategies, providing valuable insights for decision-makers.

2 - The Vehicle Routing Problem with Drones and Outsourcing

Xuan Ren, Ola Jabali, Roberto Roberti, Gongqian Liang

Recent scientific literature has shown that combining drones with trucks is effective for last-mile delivery. With the growing volumes of next-day delivery, not all customers may be served within a given day, especially when considering a limitation of the drivers' working time. To this end, we investigate the vehicle routing problem with drones and outsourcing (VRPDO), where customers are served either by a given truck-drone fleet (each truck equipped with a single drone) or by outsourcing, with each customer incurring an individual fixed cost. The objective is to minimize the transportation costs of trucks and drones as well as the outsourcing costs. We propose a variable neighborhood search (VNS) algorithm for this problem, where we represent a VRPDO solution as customer sequences. Each sequence is evaluated by solving a problem that we refer to as the fixed sequence assignment problem (FRAP). Given a customer sequence, the FRAP assigns each customer to the truck, or the drone, or be outsourced, and determines truck and drone routes, in order to minimize total costs while satisfying a maximum-duration limit. We treat the FRAP as a resource-constrained shortest path problem and introduce an exact labeling algorithm to solve it. We further develop a heuristic labeling algorithm (HLA) for the problem and reinforce the VNS by presenting filtering strategies based on the HLA. Computational results show the effectiveness of our proposed approach in terms of solution quality.

3 - Data-driven optimization of bus schedules under Uncertainties

Léa Ricard, Andrea Lodi, Guy Desaulniers, Louis-Martin Rousseau

The vehicle scheduling problem (VSP) is one of the sub-problems of public transport planning. It aims to minimize operational costs while assigning exactly one bus per timetabled trip and respecting the capacity of each depot. Public transport planning is subject to various endogenous and exogenous causes of uncertainty, notably affecting travel time and energy consumption. Despite the uncertainties involved, the VSP and its variants are usually solved deterministically to address trackability issues. However, considering deterministic travel time in the VSP can compromise schedule adherence, whereas considering deterministic energy consumption in the electric VSP (E-VSP) may lead to solutions with sub-optimal true costs (including recourse costs and the cost of ownership of battery electric buses).

This presentation proposes a methodological framework aimed at integrating uncertainties, specifically travel time and energy consumption uncertainties, into the VSP. Three distinct stochastic, data-driven mathematical models and branch-and-price algorithms are introduced to address two variations of the problem: the multi-depot VSP (MD-VSP) and the E-VSP. The objective is to find bus schedules that offer a good trade-off between operational costs and service reliability, as well as between operational costs and battery degradation in electric buses.

1 - Emergency Evacuation Routing from the Passenger Ship

Chen Li

In the past decades, real-life security problems occurring on board passenger ships in the open sea have become a great challenge. Evacuating a large number of evacuees in a limited time period is a difficult task, especially in a ship with a very complex structure inside. In this paper, we focus on the development of a fast algorithm for the emergency evacuation from a moving or sinking ship to safe points (such as lifeboats on the board). The main objective is to minimize the total network clearance time. We propose a cell-transmission-based mixed integer programming model that accounts for evacuation dynamics, congestions and balanced outflows from exits. A Lagrangian relaxation is used to decompose the problem into two subproblems. For the first subproblem, we develop a time-expanded network and propose an alternative cycle-canceling algorithm to solve it. To demonstrate the efficiency of the proposed solution technique, we provide computational results on a realistic example in the numerical part.

2 - Partial Scenario Set Cover and its Application to Emergency Planning

Shai Dimant, Sven Krumke

In the classical Set Cover problem, one is given a finite ground set Q , a collection S of subsets of Q to choose from, each of which is associated with a nonnegative cost and the goal is to choose a minimum-cost sub-collection of S whose union covers the entire ground set Q . The Set Cover problem assumes that every element of the ground set is always present. In practice, however, this may not always be the case. In the context of locating emergency facilities, the ground set corresponds to (not precisely known) emergencies. The regions in which emergencies can occur are modeled as the elements. The subset of regions in which an emergency occurs is uncertain and modeled as a scenario from the uncertainty set. For each facility, there is a set of regions that can be reached within a guaranteed response time. Following a robust optimization approach, we consider a second collection U of subsets of Q . Each set in U represents a possible scenario of the emergencies. The goal now is to choose a minimum-cost sub-collection of S such that at least a certain number of scenarios from U are covered. This leads to the Partial Scenario Set Cover problem (PSSC) which generalizes the Partial Set Cover problem, which is itself a generalization of the classical Set Cover problem. We study the complexity of PSSC, provide approximation algorithms based on LP-rounding and generalizations of the classical greedy algorithm for Set Cover.

3 - Optimal Transportation Infrastructure Protection Investment Timing for Climate Change

Elise Miller-Hooks, Ashkan Zare Hadesh

Protecting coastal roadways and other transportation infrastructure from the impacts of climate change is crucial to the long-term performance of transportation networks and the welfare of the communities they support. Climate change is responsible for sea-level rise, increased storm intensity and frequency, and larger storm surge events. Actions, like building seawalls and elevating streets or rail, are typical engineering methods for mitigating the impacts of these changes and related events. These actions often involve major capital investments and implementation schedules. Thus, it is critical to determine a best protective investment strategy and strategy implementation timing. This talk will describe OR-based methods for creating an implementable tool to support the taking of timely capital investment decisions toward transportation system protection against uncertain coastal flooding events and other risks of SLR and changing climate conditions.

4 - Locating emergency treatment sites (ETS) with decision support system (DSS) for preparedness and response to earthquake event for local municipalities

Simona Cohen Kadosh, Sagit Kedem-Yemini, Zilla Sinuany-Stern, Yuval Bitan

Although research on facility location problems is extensive, temporary medical facilities and their application have not received much attention in the domain of preparedness or the immediate response stage

Chair: Simona Cohen Kadosh

after an earthquake where a huge number of casualties will need medical treatment. In this study, we take an applicable step in developing a decision support system (DSS) for local municipalities to assist in positioning emergency treatment sites (ETS) close to destruction sites for minor injuries (over 80% of total casualties), immediately after an event, and thus reducing hospitals' loads. The DSS is based on characterization of the location network and hybrid simulation that can be applied both as a standalone emergency tool or as a planning tool for preparedness. Using a simulation/optimization model that determines the locations of ETSs, the DSS tool can compare multiple parameters and give recommendations within seconds. The proposed DSS tool includes three main components: database, decision engine and user interface, based on GIS technology (geographic information system). Preliminary feasibility study was conducted and recommends the best location for ETSs to simulating various destruction site locations with promising results. The development process is done in collaboration with a specific local municipality which will also serve as a beta site for the final DSS product. Keywords: Decision support system (DSS), Humanitarian application, Facility location

Europe's Rail MOTIONAL: Algorithms for railway planning

Stream: Public Transport Optimization

Invited session

Chair: *Giorgio Sartor*

Chair: *Dennis Huisman*

1 - Enhancing recoverable robust train routing in railway stations

Philipp Widmann, Norman Weik

Busy railway stations with multiple intersecting lines often form critical points in railway timetabling, where delays from one line can propagate through the network. Increases in railway traffic as well as plans for integrated clock-face timetables thus require careful planning of platform assignments and routes through the station to limit the effect of delays and disruptions on the overall service quality.

We present a new method for the long-term train routing problem in the station context. The goal is to find a microscopically feasible, robust train routing that is compatible with a predetermined network timetable. The method consists of a combined MILP model: A multi-commodity flow formulation ensures the feasibility of the train routing by prohibiting conflicts between chosen routes. To ensure robustness to small initial delays, we directly include a scenario-based delay propagation model and minimize the delay propagation in the worst case, thus extending previous work on recoverable robustness. We discuss modelling choices and computational performance, present results on a case study and give an outlook on possible applications for long-term infrastructure planning.

2 - Optimized Short-Term Insertion of Additional Trains Into Existing Timetables

Karim Terfasse, Nabil Absi, Stéphane Dauzere-peres, Remy Chevrier

With safer, cheaper and sustainable transportation of goods attracting major interest in recent years, rail freight is becoming increasingly attractive compared to road freight transport. For railway timetabling, this requires a better utilization of the infrastructure's capacity. However, the unpredictable nature of this growing rail freight demand poses numerous challenges to infrastructure managers, one of them being the short-term scheduling of additional freight trains within existing timetables. Indeed, residual capacity management is a good lever to accommodate freight transport requests, while ensuring safety and minimal disruption of passenger trains. Despite its significant relevance,

this problem has received relatively limited attention in the literature. This presentation aims to describe and formalize the problem, to position it within the literature and to introduce a first solution approach. Computational experiments and their numerical results will be discussed.

3 - User experience and timetable optimization

Sara Gestrelius

Many optimization models and algorithms have been proposed for the railway timetabling problem over the past decades. However, in practice, timetables are still constructed by planners with little to no optimization support. One step towards closing the gap between the state of art and state of practice is to research user experience aspects related to optimization-based timetable planning tools, and thereby better understand when and how the planners could gainfully use the algorithms in their everyday work.

In MOTIONAL WP6, RISE investigates user experience aspects that come into play when a timetable planner working for an infrastructure manager wants to use optimization/automation to solve conflicts for a train, or a set of trains, in the long-term planning process. "Participatory Design" is used to design a timetable planning support tool with optimization. The purpose of participatory design is to give a variety of stakeholders who will use the tool the opportunity to provide input on function, interaction, and visualizations to create a high-quality tool that supports their daily work. At the same time, optimization researchers will ensure that the design suggestions are likely to be implementable.

In this presentation we will share our current status of work, including knowledge gained from interviews, a hierarchical task analysis and a first sketch of the functionalities developed in the "Participatory Design" process.

4 - Incremental timetabling for handling Temporary Capacity Restrictions

Giorgio Sartor, Carlo Mannino, Bjørnar Luteberget, Oddvar Kloster

In railways, Temporary Capacity Restrictions (TCRs), such as track closures and speed reductions, can make it very difficult to operate trains according to the timetable. Depending on the severity of the TCR, the timetable might require relatively simple repairing actions (e.g., retiming, resequencing) or major modifications (e.g., cancellations, short-turning, rerouting). In general, the objective for the new timetable is to be as similar as possible to the original, but the precise definition is based on opinions and experience from the route planners, making it difficult to formalize. In contrast to most of the current literature that tries to approximate this objective, we propose the following iterative process: 1) route planners use an interactive GUI to sketch a new (potentially infeasible) reference timetable, and 2) mathematical programming is used to find a feasible timetable that is closest to the reference one. Step 1 and 2 can be repeated until the route planners are satisfied. We call this method Incremental Timetabling, to highlight the fact that route planners can iteratively steer the timetable towards the desired one, while our model simply takes care of its feasibility. We present an application of this procedure to parts of the Norwegian and Italian Railways.

Airline Applications II

Stream: Transportation

Invited session

Chair: *Silvia Padron*

1 - Optimizing Air Cargo Terminal Operations: A Model for Alleviating Unloading Bay Bottlenecks through Truck Scheduling

Arnab Chakraborty, M Vimala Rani

The efficiency of air cargo terminals is crucial for the success of the supply chain. Freight forwarders deliver cargo to cargo terminal operators (CTOs) who manage handling, customs, and loading onto airliners. Delays in truck unloading can cause bottlenecks, impacting aircraft departures. Research focuses on manpower, truck scheduling, cargo routing, and aircraft loading. Existing studies address truck scheduling challenges, adapting insights from container terminals. This study proposes a multi-server queuing system to optimize truck arrivals and unloading bay usage, aiming to minimize costs. Methodology involves modeling truck arrivals and service times, with results expected to reduce costs and alleviate congestion at unloading bays. Limitations include potential applicability only to specific airports.

2 - A two-phase stochastic approach for sizing and scheduling of battery swapping and charging of electric vehicles

Simon van Oosterom, Mihaela Mitici

The development of Electric Vehicles (EVs) has exceeded all expectations. At the current pace, opportunities will open up for electric freight transport and aviation. For these industries with tight schedules, however, long battery recharge times will be problematic. The ability to swap depleted batteries may provide an alternative. Swaps can be done quickly, and the EV can be deployed while the used battery recharges at a depot.

This paper studies scheduling operations of battery swapping and charging for a EV fleet that needs to perform a tight schedule. We propose a stochastic recourse optimization model to size the infrastructure: the charging power and the number of spare batteries. This aims to minimize the infrastructure and charging costs, given a stochastic amount of traffic to be fulfilled. The charging costs are determined in the second stage of the model, which optimizes the charging operations of the vehicles, given a day's traffic schedule. We expand on current studies by leveraging the knowledge of the traffic schedule, and by allowing for preemptive charging.

We show our method for an airline operating small electric aircraft, where swaps are done at hub airports. We use the domestic network of Norway's Widerøe Airlines of 43 airports and 56000 annual flights. We show that 4400 kW in power supply and 23 spare batteries are required for electrification. Furthermore, we show that this grants high scheduling flexibility with a smaller infrastructure.

3 - Cross-organisational Coordination in Apron operations

Silvia Padron, Maurizio Tomasella, Elisa Guardo, Daniel Guimaran, Cemalettin Ozturk

Turnaround apron operations involve a diverse array of interconnected services required for aircraft handling. Short-term planning of these services demands comprehensive coordination between the participating organisations to effectively manage the multiple interactions arising. This includes coordination efforts between aviation service providers (SPs) which are subcontracted by airlines for turnaround services and a coordinator such as the airport operator. Traditional coordination approaches largely focus on the priorities of a single stakeholder, typically airlines and airports. This paper introduces four cross-organisational coordination strategies for apron operation planning with varying levels of SP participation in decision-making. A simulation-optimisation approach based on Constraint Programming is used to model and solve the apron planning within the proposed coordination settings. Experiments suggest that equitable central coordination enhances robustness and resource efficiency of plans, while more pragmatic strategies can address specific challenges of SPs such as resource scarcity, still yielding positive outcomes in terms of schedule stability.

4 - Optimising Airport Ground Handling Operations Considering Multi-Skilled Personnel

Maurice Krauth, Henning Preis, Noah Jalowski, Nikola Bešinović

Ground handling operations at airports include a wide range of services such as baggage handling, aircraft maintenance, and passenger services. The complex associations and dynamic nature of these operations demand not just efficiency but also adaptability and precision in resource management.

This research introduces a novel approach for scheduling ground handling operations, by integrating Resource Constrained Project Scheduling Problem (RCPS) and Hopcroft-Karp algorithm to match ground handling operations and multi-skilled personnel. First, the task scheduling is addressed, which involves the adapted RCPS model to the ground handling operations, considering various constraints including time windows, personnel availability, and task dependencies. Second, the allocation of multi-qualified personnel is tackled, which introduces a modified Hopcroft-Karp algorithm to match the scheduled tasks with the applicable personnel based on their skills and availability. The overall objective is the minimisation of delays, i.e. deviations from the planned activities.

We demonstrate the performance of this approach under different conditions such as delays or resource shortage for an exemplary data set of an airport. We compare different scenarios and present the benefits of this approach.

Optimization in transportation infrastructure design and management

Stream: Transportation

Invited session

Chair: *Marie Schmidt*

1 - Using Constraint Programming to Plan Annual Maintenance of Railway Tracks

María Andreina Francisco Rodriguez, Justin Pearson, Jerker Sundström

Railway infrastructure maintenance is essential for the continuous operation of train transportation; it is costly and can only be performed in limited time windows. Maintenance companies are contracted to fix segments of railway tracks that fall below a certain quality threshold. We will be concerned with tamping, which is the process of smoothing out track irregularities.

Due to the short time windows, maintenance companies must choose which segments will be tamped each day. The tamping machines have fast travel times but are slow to tamp with significant starting and stopping times. Therefore, tamping as many contiguous segments as possible is more efficient. Before the end of a shift, the machine must return to the depot.

We use constraint programming to create multi-daily maintenance plans (and re-plans) that maximise the total length of tamped segments. Our test data is based on real-life planning requirements with instances of continuous tracks of approximately 120 KM divided into more than 800 segments of varying sizes from 30 to 400 meters. Our results are promising, and we can quickly find near-optimal solutions using Google OR-Tools. Our model has several non-obvious improvements, such as symmetry breaking and over-approximations to the upper bound, significantly improving solving time.

2 - Network Design for Evacuation Preparedness under Cost and Travel Congestion Considerations

Halit Uster, Nadere Mansouri

We present an evacuation network design problem under cost and travel congestion considerations while incorporating worst-case evacuation time for the evacuees. Employing a time-expanded network, we model for effective and controlled evacuation by determining active shelter locations and evacuee routes that can be implemented in the preparedness stage in response to foreseen extreme events, such as hurricanes and flooding. To solve our model, we devise an efficient Benders Decomposition (BD) framework with convergence enhancements for solving large-scale instances while also taking advantage of specific characteristics of the problem. We design and implement an experimental study to test our BD technique and to conduct sensitivity analysis for various parameters and model validation using data from Central Texas.

3 - Capacitated Multi-Enabler Transportation Network Design for Autonomous Trucks

Ebrahim Mohammadi, Marie Schmidt, Rob Zuidwijk

Autonomous trucking is expected to increase transportation productivity, especially for long-haul transportation. Providing infrastructure and enablers with enough capacity to support this type of transportation is essential for the successful deployment of autonomous trucks. In this paper, we investigate the capacitated transportation network design problem for autonomous trucks. We assume that the autonomous network requires several types of enablers with limited capacity to support autonomous truck transportation. A new mixed-integer linear programming model is proposed to locate various capacitated infrastructures and enablers required for long-haul autonomous transportation over multiple periods. This model strategically integrates the location decisions of multiple enablers over the planning horizon. Enablers, such as refueling stations, emergency maintenance stations, and transfer hubs, are characterized by unique operational features and capacity considerations. The model is implemented numerically on benchmark cases, such as the Sioux Falls network, and sensitivity analysis for key parameters is provided.

1 - Accelerated Static Hedging Method for Pricing American Options

Lung-fu Chang

This article provides an accelerated static hedge portfolio (SHP) method for evaluating American options based on stochastic volatility and double jump processes. Our proposed model is a generalization of the static hedge portfolio approach of Derman, Ergener, and Kani to evaluate American options based on the Richardson extrapolation. Numerical results show that the numerical efficiency of our accelerated static hedge portfolio approach is comparable to the least-squares Monte Carlo simulation method. Numerical results demonstrate that our proposed method is efficient and accurate in evaluating American options with stochastic volatility and double jump processes.

2 - Portfolio selection based on the Herd Behavior Index

Churui Li, Daniel Linders, Wing Fung Chong

In this paper, we propose to determine optimal portfolios using the Herd Behavior Index (HIX, Dhaene et al. (2012)). The HIX is a diversification measure that provides information about the extent to which stock prices move together in the same direction. The optimal

minimum-HIX, as well as mean-HIX, portfolio can be seen as the most diversified one since it has the lowest degree of co-movement. We make use of a reformulation method for determining the minimum-HIX, and mean-HIX, portfolios, as their closed-form expressions are not readily available in a general setting. This also allows us to study the mean-HIX efficient frontier. We prove the existence of the minimum-HIX, and mean-HIX, portfolios in the general setting, and provide their closed-form expressions in the two-stock case. We also study how to determine the minimum-HIX, and mean-HIX, portfolios when short-selling is allowed. This requires us to generalize the definition of HIX in order to ensure that the (theoretical) comonotonic portfolio always exceeds the (actual) portfolio in convex order.

[1] Dhaene, J., Linders, D., Schoutens, W. & Vyncke, D. (2012), 'The herd behavior index: A new measure for the implied degree of co-movement in stock markets', Insurance: Mathematics and Economics 50(3), 357-370.

3 - You Shall Not Pass - Minimizing false-positive ensemble classification through threshold optimization

Richard Oberdieck, Ruben Menke, Christian Møller Karsten

As a bank, we handle millions of transactions a day. Almost all of these (>99.99%) are completely fine and legitimate transactions. However, every once in a while a sanctioned entity is either trying to send or receive money with a payment we process. We want, and are legally required, to stop such payments. Due to the high volume of transactions a day, algorithms play a crucial role in flagging potentially suspicious payments. If any of these algorithms judge there to be a match to a sanctioned entry, the payment is investigated manually.

This poses a challenge though: the number of true positives is very low, so even the best algorithms will mostly flag false positives (>95%). This means almost all of the payments an analyst goes through are fine, they just have an unlucky similarity to a sanctioned entity. To reduce this issue, the algorithmic thresholds have to be as tight as possible, while still finding all the true positives.

In our presentation, we will show how this problem can be posed as a mixed-integer programming problem and the results it yields. We also discuss how to extend the formulation to allow for a risk-based approach, where a certain number of misses of true positives are allowed, in order to further reduce the number of false positives. This results in a fascinating pareto front, which is used as a basis of discussion around price of catching all true positives.

Real-Life Applications in Routing

Stream: VeRoLog - Vehicle Routing and Logistics

Invited session

Chair: Martin Klingebiel

1 - Optimization of Road Transport With Crossdocks: A Case Study at Inditex With Matheuristics

Julio Lopez, Julio González-Díaz, Telmo Costa Carballo

With a complex network of warehouses and depots, optimizing ground transportation is a goal for sustainability and efficiency. Our problem aligns with CVRPTW, a Vehicle Routing Problem with Limited Capacity and Time Windows for pickup and delivery. However, since most warehouses must deliver to most depots, freight exchanges at predetermined nodes in the network play a leading role in an optimal solution to the problem.

To tackle this challenge, our initial approach involved modeling the problem using direct mixed integer and linear programming techniques. We carefully tailored the model to meet our additional requirements, with emphasis on accurately representing the exchange of cargo at designated points.

However, as expected, this problem with our logistics network and crossover points is not solvable in our time requirements due to its inherent computational complexity. To address this challenge and speed up the solving process, we explored some math-heuristic approaches, acknowledging potential compromises in optimality.

2 - Travel and Modify: Travelling Salesmen Problem in Environments Altered by the Salesman

David Woller, Miroslav Kulich

The presented work is inspired by a real-world application in autonomous open pit mining. A drill rig is tasked with digging a large number of blast holes, organized in a tight semi-regular pattern. Digging each hole generates a pile of excess material, that represents a new obstacle for the drill rig. The goal is to determine the piles placement and drill all holes, while minimizing total distance traveled, avoiding all already placed obstacles and getting stuck between them. We propose the concept of self-deleting graphs, where visiting a vertex causes deletion of a predefined set of edges. This formalism can capture the dynamic addition of obstacles in the motivating application, which is dependent on the previous drill rig path. On these graphs, we formulate variants of the classical Hamiltonian Cycle Problem and Traveling Salesman Problem and design novel solvers for these problems, both exact and heuristic. In the next step, we address the problem of pile placement in a close vicinity of each hole, given a fixed tour. We formulate the problem as Path-Conforming Circle Placement Problem, propose a heuristic solver and derive solution bounds. Finally, we combine both problems together and fully address the original application as the Traveling Salesman Problem with Circle Placement, which we solve by combining the already developed approaches. The resulting solver is evaluated on several newly created datasets mimicking the real-world applications.

3 - Route Optimization of Freight Transportation Under Multiple Real Operational and Legal Constraints

Alfredo G. Hernandez-Diaz, Ana Pérez Rubio, Cristina Tobar, Francisco Javier Diego Martín

The objective of the work is to help a large international transport operator in the optimized planning of its fleet, which constantly performs full and break-bulk routes, as well as groupages adapted to any requirement of its customers. We are faced with a periodic vehicle routing problem with capacities and time windows (PCVRPTW) with some additional requirements and constraints such as: multiple-week planning, time windows for available days and hours, maximum daily and weekly driving and working times, daily, weekly and bi-weekly breaks for drivers, maximum distance between an unloading and the next assigned load, the first and last load of each week must be the least possible distance from the drivers' homes, the customer wants all vehicles to travel at least 3500 km weekly and reached this value wants to balance the distances, among others. One of the main challenges lies in the logistics operator's desire to reschedule all pending tasks every 15 minutes, since, on the one hand, they are constantly receiving new orders and, on the other hand, unforeseen incidents arise that alter the original schedule. Therefore, the algorithm must be fast enough to provide quality solutions in approximately 4 to 5 minutes. This paper will show the mathematical programming model, the implementation performed with Hexaly, and the solutions obtained in real instances, obtaining the first feasible solutions in a few seconds and quality solutions in a few minutes.

4 - A Branch-and-Price-Algorithm for Tactical Maintenance Planning for Rotor Blades on Onshore Wind Turbines

Martin Klingebiel

We address the maintenance planning for rotor blades on onshore wind turbines at a tactical level, motivated by the case of a German onshore wind turbine manufacturer. The goal is to select maintenance teams from external service providers and assign maintenance tasks for a maintenance season while minimizing the total costs. The operative scheduling of the maintenance tasks and routing of the maintenance teams are anticipated to determine the capacity needs. We consider team-specific work time regulations, locations, qualifications, cost rates, means of transport, task-specific time windows, and weather

conditions. However, planning such a maintenance season is very challenging. For this reason, we formulate a mixed-integer linear problem for routing and scheduling the heterogeneous teams to perform maintenance tasks at different locations with minimum total costs. We propose a branch-and-price algorithm approach based on a Dantzig-Wolfe decomposition to solve it. The pricing subproblems are solved using a labeling algorithm. The approach is implemented using the SCIP framework. We present the underlying problem decomposition, implementation, and first numerical results using a state-of-the-art commercial solver as a benchmark.

1 - Fast Algorithms for Capacitated Continuous Pricing with Discrete Choice Demand Models

Tom Haering, Fabian Torres, Michel Bierlaire

This research introduces the Breakpoint Exact Algorithm with Capacities (BEAC) and the Breakpoint Heuristic Algorithm (BHA), both of which offer substantial advancements in solving the choice-based pricing problem (CPP) with and without capacity constraints. The BEAC, enhancing the Breakpoint Exact Algorithm (BEA) with a capacity management strategy, outperforms the state-of-the-art mixed-integer linear programming (MILP) approach by 20 times in computational speed. The BHA, employing a coordinate descent method, excels in high-dimensional scenarios, showing remarkable efficiency in both capacitated and uncapacitated cases. Notably, it outpaces the MILP by a factor of 100 to 5000 for the capacitated case, and the state-of-the-art Branch and Benders Decomposition approach by several orders of magnitude for the uncapacitated case, while maintaining an average optimality gap of less than 0.2%. The dynamic line search extension of the BHA succeeds in identifying the global optimum in all tested instances, albeit with a significant speed reduction. For future research, other extensions of the BHA to escape local optima should be considered.

2 - A tactical time slot management problem under mixed logit demand

Dorsa Abdolhamidi, Virginie Lurkin

The growth of e-commerce has led to increased requests for home deliveries, including attended home deliveries for subscription-based platforms, which require frequent customer presence at home. To accommodate customer availability, many online retailers offer different delivery time slots. Providing these time slots is convenient for customers but results in higher uncertainty for the retailer. This paper introduces a novel model tailored for subscription-based e-retailers in which customers' decisions regarding delivery slots and their corresponding impact on routing costs are explicitly considered. The slots' assortment and discounts on prices are considered control variables in our model. Our research employs a mixed-integer linear programming framework integrated with a mixed logit model, capturing customer preferences' stochastic and diverse nature in delivery time slots. We use an adaptive large neighborhood search to be able to solve this problem for large instances of this problem. Numerical experiments are conducted to show the effectiveness of these approaches. Results indicate the importance of accounting for the uncertain heterogeneous behavior of customers when deciding about the assortment and price discount rates of time slots.

3 - Modern column generation for the estimation of non-parametric discrete-choice models

Luciano Costa, Gerardo Berbeglia, Claudio Contardo, Jean-François Cordeau

Discrete choice models (DCMs) provide probabilities for individuals choosing a certain alternative when faced with a set of limited options. DCMs can be parametric or non-parametric. Parametric models are easier to estimate but require assumptions about individuals' preferences, while non-parametric models rely solely on training data without any assumptions. Ranked-list methods are popular non-parametric models and capture individuals' behavior by associating them with preference lists of options sorted in decreasing order of preference. Individuals are assumed to always choose the option best placed in their preference list when confronted with an alternative. Despite the generality and simplicity of ranked-list methods, a major drawback associated with them is the exponential increase in the number of potential lists. Column generation (CG) can be employed to address this issue, with the CG subproblem being modeled as a generalized linear ordering problem (GLOP). In this work, we propose a dynamic programming algorithm to solve GLOPs. The proposed method is generic and capable of handling different settings without requiring drastic changes in its implementation. When incorporated into maximum likelihood and minimum L1 estimators, our algorithm efficiently generates preference lists. The algorithm performs well when facing instances with several observations, which is crucial as non-parametric choice models heavily rely on data volume for accurate estimations.

4 - Data-driven advertising policy on e-commerce platform with budget constraint

Yunzhi Cao, Houmin Yan, Yedong Wang

Advertising is one of the crucial tools for retailers on the e-commerce platform for promotion, such as Amazon. This study focuses on the joint bidding and pricing policy for retailers subject to budget limitation under multiple periods. The bidding is for the impression on the sponsored advertising list. The click-through rate and conversion rate functions with respect to bid and price are learned and estimated based on historical data. We formulate a stochastic model and construct a dynamic programming formulation. We prove the existence of the unique optimal solution and characterize the structure of an optimized bidding and pricing policy. Through theoretical analysis and a case study, we investigate the relationships among the optimal policy, value function, and key factors, and demonstrate the effectiveness of the optimal policy and the proposed dynamic model.

RCPSP and extensions

Stream: Project Management and Scheduling
Invited session

Chair: Norbert Trautmann

1 - Improved Results on RCPSP Using Failure-Directed Search in Constraint Programming

Zdenek Hanzalek, Vilem Heinz, Petr Vilím

The Failure-Directed Search (FDS) was introduced as a state-of-the-art algorithm for proving optimality and lower bounds for scheduling problems such as Job Shop Scheduling Problem (JSSP) and Resource-Constrained Project Scheduling Problems (RCPSP). We re-implemented the FDS algorithm in a new CP solver called OptalCP to understand its notable performance better and use these insights to improve its performance further. Despite its genericity and simplicity, FDS proved optimality or solved optimally numerous scheduling instances that were open for decades. In this paper, we investigate the properties of FDS. Experimental results show the improved FDS is 1.7x faster on JSSP and 2.1x faster on RCPSP benchmarks and is 3.5x times faster on JSSP and 2.1x times faster on RCPSP than the state-of-the-art FDS algorithm in IBM CP Optimizer 22.1. The new FDS improved existing lower bounds of 66 out of 78 and 43 out of 78 randomly picked JSSP and RCPSP instances, respectively.

2 - Bi-objective Multi-skill Resource-Constrained Project Scheduling with Resource Efficiency

Laura Anton-Sanchez, Javier Alcaraz, Francisco Saldanha-da-Gama

A variant of the resource-constrained project scheduling problem (RCPS) is the multi-skill RCPS (MS-RCPS) where each resource has one or several skills and each activity may require several resources with certain skills. The standard goal of the MS-RCPS is to determine a start time and the allocation of resources for each activity to complete the project as soon as possible, i.e., to minimize the makespan. In this work, we consider a more realistic scenario where all the resources do not master all their skills with the same efficiency (this is often the case, for example, when human resources are involved). To model this situation, we consider that a more efficient resource can contribute with more than one resource-unit to the execution of an activity. In addition, we consider the cost for resource usage and address this new version of the problem from a multi-objective perspective, minimizing both the makespan and the total cost. We present an optimization model for this new problem and develop exact methods to find the set of Pareto solutions.

3 - Exploring New Insights into the Multi-Mode Resource-Constrained Project Scheduling Problem

Sofía Rodríguez Ballesteros, Javier Alcaraz, Laura Anton-Sanchez

This study introduces a new variant of the Multi-Mode Resource-Constrained Project Scheduling Problem (MRCPS), integrating two common real-world aspects: time-dependent resource costs and time-varying resource capacities. Time-dependent resource costs imply that costs vary based on resource utilization time, while time-varying resource capacities involve resource availability across different planning horizon periods. Employing a multi-objective framework, the study aims to minimize both the makespan and the total resource usage costs. A mathematical formulation is presented, and attempts are made to identify the Pareto front (PF) using an exact method. However, due to the problem complexity, a metaheuristic approach is developed to approximate the PF. We propose a new NSGA-II based metaheuristic, designing a novel solution encoding and the corresponding genetic operators to accommodate the new problem elements. Furthermore, we propose a fitness function to handle infeasible individuals within the multi-objective context. Computational experiments are conducted using instances derived from existing literature, demonstrating the algorithm's strong performance.

4 - Workload-Based Extensions of Mixed-Integer Programming Models for Resource-Constrained Project Scheduling

Norbert Trautmann, Jonas Saube, Mario Gnägi

Several mixed-integer programming models have been proposed for scheduling project activities under predefined resource capacities and precedence constraints. We introduce a model expansion that considers aggregated capacity limitations. A computational evaluation for three state-of-the-art models from the literature shows that the extension is advantageous for each of the tested models.

Location under uncertainty

Stream: Locational Analysis
Invited session

Chair: Juan A. Mesa

1 - Minimizing maximum regret via robust optimization in a two-stage facility location problem under demand uncertainty and facility cost uncertainty

Ronald McGarvey, Andreas Thorsen

Consider a situation in which an initial decision is made to prepare a set J of locations for potential future use supporting a set of customers under uncertain demand and uncertain future facility construction costs. Once the demand is revealed, the decision maker then makes a recourse decision selecting the set K of actual facility locations to be opened, where K is a subset of J . We present robust MILP formulations of this problem, assuming an objective function that minimizes the maximum regret. A budgeted uncertainty set is assumed, in which the realized demand is assumed to be equal to a most-likely value plus a potential positive deviation minus a potential negative deviation. Use of a regret-based objective function has a significant impact on the solution time when directly solving with a commercial MILP solver. In part, this is due to the fact that we assume demand could potentially be less than the expected value at any customer, which is relevant for a regret-based objective (but not for a total cost-based objective). We then develop a computationally-efficient solution algorithm, based on a column-and-constraint generation (CCG) approach, and examine numerical test instances to identify the relationship between problem conditions and solution structure.

2 - The Stochastic Capacitated Facility Location Problem with Backlogs: Exact and Heuristic Algorithms

José Emmanuel Gómez-Rocha, José-Fernando Camacho-Vallejo, Eva Selene Hernández Gress, Cipriano Santos

The Capacitated Facility Location Problem (CFLP) is a well-known combinatorial optimization problem extensively studied in the field of location sciences. It has numerous applications in industrial engineering, humanitarian logistics, telecommunication networks, and other domains. Incorporating uncertainties in demands, stochastic programming emerges as a suitable approach to address this problem. However, the main drawback is that due to stochasticity, not all customer demand may be satisfied. To address this issue, we introduce the concept of backlogs into the CFLP. As a result, the CFLP with backlogs and normally distributed demands is proposed, where the cost of losing a customer is considered as a penalty cost in the objective function. To solve the problem we propose an exact and a heuristic method. The exact method is a Benders decomposition based on Branch-and-Cut. The heuristic method follows a Fixing-First scheme based on pricing strategies that efficiently solves the problem within a reasonable computational time. The effectiveness of the proposed algorithms is evaluated by comparing it against a deterministic equivalent solution given by the general-purpose solver Gurobi. Computational experiments are conducted on a set of challenging instances using a sample average approximation scheme. To validate the applicability of the problem under study, a real case study involving Mobile Health Clinics (MHCs) located in Mexico was analyzed.

3 - Locating multiple facilities on a network to maximize the sum of expected utility

Ken-ichi Tanaka

We consider the problem of locating multiple facilities on a network. It is assumed that all facilities are owned by a single decision maker, and each facility has an attractiveness. The users' choice behavior of facilities is described by multinomial logit model where the utility of each user is given by an increasing function of the attractiveness of each facility and a decreasing function of the distance to the facility. We consider the problem of finding facility locations that maximize the sum of the expected utilities for all users. This problem is a natural extension of the p -Median problem by assuming probabilistic choice behavior. The proposed model is formulated as a nonlinear integer programming problem. We present two solution approaches. One is based on a formulation in which the objective function is approximated by a set of linear functions, and the other is a heuristic method based on vertex substitution. Using example road networks, we investigate how the distance decay coefficient affects the locational patterns of facilities. In addition, we present a generalized problem involving optimization of the facility size under the budget constraints.

Chair: *Eduardo Lalla-Ruiz*

1 - Just-in-Time sailing for container ships

Rommert Dekker

Just-in-Time sailing is a recently introduced concept by the IMO to avoid ships waiting before terminals. In this talk we investigate to which extent this concept saves money as well as CO2 emissions. First we consider the case without arrival slots and investigate how much slowing down saves. Secondly we consider the case that ships also have information about the ships behind them. Finally we consider the case where terminals define arrival slots at a tactical level with penalties for late arriving. We consider several strategies for ships and investigate the case with two shipping lines with different arrival reliability.

2 - Model and a Memetic Algorithm for Berth Allocation in Multipurpose Inland Waterway Terminals

Jiyin Liu, Adnan Pasha, Rajat Rastogi

Inland water transport terminals, especially those in developing countries, are commonly used for handling multiple cargo types. Berth allocation in such multipurpose terminals has special features different from that in specialized seaport terminals. While existing berth allocation research primarily focused on specialized terminals, this study investigates the discrete berth allocation problem in multipurpose inland water terminals considering the diverse cargo types and unique operational constraints involved. The problem is first formulated as a mixed integer linear programming model with the objective of minimizing the waiting and completion times of barges. A memetic algorithm is developed to obtain near-optimal solutions efficiently. Real-world data from an Indian inland water terminal are used to conduct computational experiments which demonstrate the model's effectiveness and the algorithm's efficiency. The developed method has the potential to be incorporated into the operations planning system of inland water terminals in developing nations to help improve their productivity.

3 - On the berth allocation problem under disruptive events for a multipurpose terminal

Rosa G. González-Ramírez, Karol Suchan, Eduardo Lalla-Ruiz

Maritime ports are strategic nodes in the global transport chain and play an important role in the efficiency of cargo transport as transfer nodes. One of the most important planning decisions at the seaside interface is the berth allocation problem (BAP), which consists of determining the berths' assignment to the incoming vessels in a port terminal such that spatial and temporal constraints are respected while minimizing vessel handling times. In this paper, we address the berth allocation problem considering the operations of a multipurpose terminal in Chile. Several terminals operate in the port and there exists a regulation that determines priorities for the incoming vessels and preemption of vessels is allowed. The port has recently suffered from weather surges or swells which resulted in port closures that affect the operations and seaside plans, in addition to more typical disruptions such as delays in the arrival times of vessels and black sailings. We propose a rolling horizon methodology and an extension to the generalized set partitioning-based formulation proposed by Christensen and Holst (2008). We generated some instances to test the proposed approach based on historical data provided by the port and derive some recommendations. References Christensen, C. G., & Holst, C. T. (2008). Berth allocation in container terminals. Master's thesis, Technical University of Denmark.

4 - A novel formulation and benchmark suite for the container stowage planning problem

Agnieszka Sivertsen, Line Reinhardt, Rune Jensen

Maritime transportation, crucial for global trade, moved 165 million twenty-foot equivalent units in 2022, with a stable annual growth of 3.5% over the past two decades [1]. Despite being the most eco-friendly mode of cargo transport [2], container stowage optimization can achieve further efficiencies and CO2 reductions. Despite its economic and environmental importance, the Container Stowage Planning Problem (CSPP) has seen limited research attention, with only 200 related publications since the 1970s [3]. The main challenges come from the industry's insularity and the scarcity of publicly available data, leading to oversimplified and insufficient models. In partnership with Sealytix, we have created the Representative Container Stowage Planning Problem (RCSP) to make the CSPP more accessible. Sealytix's industry knowledge has helped capture essential aspects without unnecessary complexity. The RCSP is partnered with a comprehensive benchmark suite using real-world data, evaluated with a Large Neighborhood Search algorithm.

Optimization Model for Novel Risks in Finance and Climate

Stream: OR in Banking, Finance and Insurance: New Tools for Risk Management
Invited session

Chair: Nikolas Topaloglou

1 - Climate transition risk to sovereign debt sustainability

Veronica Mammetti, Giacomo Morelli, Stavros A. Zenios

We incorporate integrated assessment models (IAM) of climate change in stochastic debt sustainability analysis (DSA) and study the effects of transition risk on sovereign debt dynamics. Following recent literature on the effects of climate transition on default probabilities, we introduce a climate risk premium into standard DSA. We calibrate this climate transition-debt channel for several eurozone sovereigns. A calibration spanning the Paris Agreement documents a significant increase in transition risk following this agreement. We then use ensembles of IAMs to obtain forward-looking projections of the climate premium under the orderly and disorderly scenarios from the Network for the Greening of the Financial System. Using the combined IAM-DSA model, we identify adverse debt effects from the increasing transition risk across countries and all IAMs. The adverse effects materialize earlier under the orderly transition, but under disorderly transition, they are significantly more impactful. We find, with high confidence level, that modest extra fiscal effort can maintain debt sustainability under orderly transition, albeit this is not the case for disorderly transition. Our analysis also identifies significant quantitative differences across IAMs, although the general conclusions remain consistent across models. We identify significantly different effects among countries depending on their level of debt and climate exposure.

2 - An explanation of under-diversification puzzles through ambiguity tastes and beliefs

Stavros A. Zenios, Somayeh Lotfi

We developed portfolio selection models with heterogeneous ellipsoidal ambiguity sets of correlated returns and a performance ratio

without a normality assumption and explained the equity home puzzle through the ambiguity channel. First, we develop a parsimonious model without risk or ambiguity aversion parameters and show it to be consistent with second stochastic dominance. We generalize the model for continuous ambiguity aversion. These models account for perceived ambiguity (beliefs) and ambiguity aversion (tastes) as potential puzzle explanations.

Taking the models to the data, we obtain optimal allocations matching those of international investors in 21 developed and 19 emerging markets. This is shown both for worst-case ambiguity aversion under perceived ambiguity well within the market estimated ambiguity sets or for mild ambiguity aversions given the market-estimated ambiguity sets. The global average ambiguity aversion is about 0.6, statistically different from the ambiguity-neutral 0.5. Our estimates of ambiguity aversion from the observed asset allocations for a large sample of countries closely match the scant experimental evidence from US, Dutch, and Chinese population samples. Our findings are robust to two fundamentally different methods for measuring ambiguity.

The worst-case model applied to a homogeneous ambiguity set predicts lower ambiguity with less diversified portfolios. We verify this on a large dataset of US household portfolios, and by running

3 - Recent Results in Contextual Portfolio Optimization

Roy Kwon, Andrew Butler

'Smart Predict and Optimize' is an emerging paradigm where the parameters and optimal solutions for an optimization problem are jointly determined. We present some recent results using this paradigm for mean-variance optimization. We show that the integrated (joint) approach can result in parameter estimations and optimal solutions that perform better out of sample than those obtained from the 'predict or estimate first, then optimize' approach. Computational challenges will be discussed which motivates the development of decomposition methods based on the alternating direction method of multipliers (ADMM) for the optimization layer in the neural network that represents the integrated approach.

Vehicle Routing Under Uncertainty 1

Stream: VeRoLog - Vehicle Routing and Logistics

Invited session

Chair: Alice Raffaele

1 - Vehicle Routing With Stochastic Demand, Service and Waiting Times - The Case of Food Bank Collection Problems

Sonja Rohmer, Meike Reusken, Gilbert Laporte, Frans Cuijssen

Food banks play an important role in fighting food waste as well as alleviating hunger, yet often struggle to effectively collect all food donations due to their highly uncertain operating environment. Addressing this issue, this research introduces the capacitated vehicle routing problem with travel time restrictions and stochastic demand, service and waiting times, which can be generalized to other routing applications. The problem aims to determine a minimum number of vehicles, while cost-effectively planning routes for these vehicles so that each route violates the vehicle capacity and the travel time limit only with a very small probability. The resulting problem is highly complex and thus solved by means of a matheuristic, which decomposes the problem into its natural decision components. As such, it first determines the number of districts into which the service area should be partitioned, before allocating each customer to exactly one district and then plans a route for each district. Extensive numerical experiments, involving both randomly generated and real-life instances, demonstrate

the matheuristic's effectiveness in solving instances with up to 100 customers. In addition, we present valuable managerial insights by applying our matheuristic to real-life instances from Dutch and Canadian food banks.

2 - Deep Controlled Learning for the Delayed Time Window Assignment and Vehicle Routing Problem

Layla Martin, Sifanur Celik, Albert Schrottenboer, Tom van Woensel

When delivering chilled/frozen, expensive, or odd-sized goods, customers must be present to receive the shipment. In current operations, this often results in failed delivery attempts or considerable inconvenience for customers who need to be present long, often the entire day. To alleviate this inconvenience, logistics service providers (LSPs) moved towards communicating time windows, either directly after the customer shipment is received or batched the day before. Longer waiting for a time window poses an inconvenience for customers. We suggest a scheme in which the LSP decides (i) whether to assign a time window to a newly arriving customer, and if the LSP assigns a time window, also if some previously postponed customers shall also receive a time window, (ii) the actual time window, and (iii) the routes satisfying the time windows. To solve the resulting semi-Markov decision process, we adapt three solution methodologies: Deep Controlled Learning, the Rollout Algorithm, and the Multi-Scenario Approach. We show that Deep Controlled Learning manages to balance solution quality and runtime. We further find that customers located very close or very far from the depot receive time windows quickly, while other customers have to wait longer. On the other hand, customer arrival time does not influence the waiting time substantially.

3 - Robust Policies for a Multi-Stage Fleet Sizing Problem Under Demand Uncertainty

Alice Raffaele, Demetrio Laganà, Roberto Musmanno, Roberto Roberti

In a stochastic dynamic setting over a planning period of days, we consider a set of customers, each placing exactly one order on a known day. Each order is associated with an uncertain demand and can be either served or outsourced by paying a penalty. Customers have day windows that, if some flexibility is allowed, can be extended by anticipating or delaying the service by paying a penalty. At the end of each day, we decide which pending orders to serve on the following day by exploiting a heterogeneous fleet of vehicles. The goal is to minimize the total costs due to fleet sizing and customer inconvenience for anticipations, delays, and outsourcing. We formulate the problem as a Markov decision process and solve it with Approximate Dynamic Programming by integrating robust-optimization techniques in Direct Lookahead Approximation policies. Our study is motivated by an on-demand waste collection service. Nevertheless, the problem has applications in many other contexts, such as reverse logistics and technician routing [1, 2].

Ulrike Leopold-Wildburger

By studying the history of scientists respectively scientific discipline developments a series of background issues can be explained. Jakob Krarup is THE person who was able to connect his ideas with other disciplines as well as being the key to future development directions. Operations research as a quite young discipline, nevertheless full of contradictions, makes it mandatory to be overviewed by excellent connoisseur like Jakob had been. He was able to describe the evolution of OR in terms of developing applied methods of decision making in socio-technical systems, by using new methods explaining contemporary demand of army, society, industry, economics as well as politics. As a well known scientist, as an unique teacher and a really good friend the university of Graz will always remember him. The Austrian OR society ÖGOR is proud to list him as a honorary member since 2020.

2 - Some thoughts of sincere gratitude to Professor Jakob Krarup - our mentor and friend

Gerhard-Wilhelm Weber

This talk adds some professional and, not least, personal elements to the appreciation of Professor Jakob Krarup. They cover the period since 2000, address some of his important scientific achievements, some joint conferences and conference organizations, especially within EURO and EUROPT, and in particular his warm-hearted and loyal, caring and fatherly personality that manifested itself in the minds and hearts of many people and forever in EURO, IFORS and all Operational Research.

3 - Jakob Krarup. Very personal remarks

Stanislaw Walukiewicz

The story of the DAPS society and participation of other foreigners at the DAPS activities.

4 - Cooperation with Jacob Krarup, his impact for OR development in Baltics

Leonidas Sakalauskas

A talk about cooperation with Jacob and his impact to developing LitORS OR initiatives, the XXI ESI in 2003, Neringa, Lithuania, XXV EURO Conference, 2012, July, Vilnius, Lithuania and others.

5 - A few souvenir photos of our friend Prof. Jakob Krarup, a remarkable personality and great supporter of the EURO member societies

Lidija Zadnik Stirn

Our friend Prof. Jakob Krarup was a remarkable person whose impact on our community, commitment, vision, leadership, wisdom, integrity, inclusiveness, efforts to foster collaboration, willingness to listen to every voice, kindness, empathy and humor will remain with us forever. He was the heart and driving force of the EURO family, developing friendships between many members that often extended to families. His words were: "Without a doubt, friendship is what will remain most precious to me when everything else is forgotten". Not only his ideas for the development of EURO and the challenges that need to be overcome if OR is to be successful in the future, but also his Christmas and birthday cards, numerous photos of his family and friends, his garden, nature, even sport and music, stories of past (especially EURO) events will remain as memories of Jakob.

1 - Charting the Course: How to power decision making in the Maersk transportation network with decision science

Berit Brouer

This presentation will highlight how decision science can power decision making on the journey from designing a global ocean transportation network serving 100000+ customers across 130 countries to the intricate orchestration of schedules for 700+ vessels to transport our customers goods and ensure availability of equipment to enhance our customers supply chains all the way. At every phase decision science can play a pivotal role in increasing consistency and quality of decision making. We will also delve into the orchestration of problem solving between the different phases.

The presentation will emphasize how the implementation of models and algorithms is really just ten cents a penny - successful implementation of decision science necessitates harmonizing with organizational dynamics, processes, and technological frameworks. We'll explore the evolution of decision science products at Maersk emphasizing the criticality of obsessing about customer and business outcomes through performance and process metrics needed to sustain the vitality and health of decision science products.

(Deep) Reinforcement Learning for Combinatorial Optimization 3

Stream: Data Science Meets Optimization

Invited session

Chair: [Yingqian Zhang](#)

Chair: [Kevin Tierney](#)

1 - Optimizing a Multi-echelon, Multi-Product, Lost-Sales Inventory Management System through Deep Reinforcement Learning

Fatemeh Fakhredin, Joern Meissner

Our study is going to address a lost-sales inventory management problem spanning multiple echelons and products, aiming to maximize network profit while determining optimal quantities from upstream suppliers. We utilize deep reinforcement learning (DRL) to optimize inventory management in these complex supply networks.

We begin by constructing a complex inventory management model accommodating lost sales and intricate cost structures. Employing DRL, we develop a framework to tackle this problem and evaluate its efficacy.

Our investigation extends to various scenarios, encompassing changes in lead time, fixed and sourcing costs, holding expenses, lost sales penalties, and demand variations. Therefore, the overarching research question we will attempt to address is: Does deep reinforcement learning produce superior policies for the multi-echelon, multi-product, lost-sales inventory management problem, in comparison with standard reinforcement learning?

2 - Learning to Generate Hard Instances: Towards Robust Solutions for Vehicle Routing Problems

Xia Jiang, Yaoxin Wu, Yingqian Zhang

Deep models have shown promising results in solving vehicle routing problems (VRPs). However, existing models are often trained on instances from specific distributions and their worst-case performance is largely underexplored, thereby hindering the understanding and improvement of their robustness. In this paper, we present a generic

framework to generate hard instances for obtaining robust VRP solutions. Given a pretrained deep model, we first develop an attack method that comprises an autoregressive sampling network (ASN) and a hardness measurement network (HMN). The two networks are trained alternately by reinforcement learning, aiming to generate hard instances for the given deep model and gauge the attack effect (i.e., hardness) of the instances, respectively. Then, we propose a simple yet effective training algorithm to robustify the deep model, which is progressively replaced by the continually trained HMN. Experimental results show that the attack method significantly degrades the performance of various deep models and conventional heuristics. Moreover, the training algorithm showcases the ability to enhance the robustness of the deep model, demonstrating its promising zero-shot generalizability.

3 - AM4FJSSP: An Attention Model formulation for the Flexible Job Shop Scheduling Problem

Lin Xie

The flexible job shop scheduling problem (FJSSP) is a complex combinatorial optimization CO problem (COP) in manufacturing, involving the allocation of operations across multiple machines while considering varying processing requirements and machine capabilities. In contrast to normal job shop scheduling operations in the FJSSP may be processed on multiple machines with different processing times, introducing additional complexity. Current deep reinforcement learning implementations for the FJSSP make use of graph neural networks, which are limited to local message passing and therefore underperform compared to the attention model (AM) on various COPs. Especially for the FJSSP with complex inter and intra node relationships, the self-attention mechanism of the AM could enhance feature representations. However, the AM is defined for problems with a single entity type, like customer nodes in the TSP, whereas machines and operations of the FJSSP pose different node types in a complex heterogeneous graph. Therefore, this work proposes an extension of the AM, integrating self- and cross-attention blocks to allow for message passing between all nodes and thus to capture inter and intra node relationships. Further, we present a factorized action-space formulation for the FJSSP, which - other than the composite action-space used in current implementations - does not grow quadratically. Consequently, a better sampling efficiency and scalability of our approach is to be expected.

4 - Job Shop Scheduling Benchmark: Environments and Instances for Learning and Non-learning Methods

Yingqian Zhang, Robbert Reijnen, Yaoxin Wu, Zaharah Bukhsh

We introduce an open-source GitHub repository containing comprehensive benchmarks for a wide range of machine scheduling problems, including Job Shop Scheduling (JSP), Flow Shop Scheduling (FSP), Flexible Job Shop Scheduling (FJSP), FJSP with Assembly constraints (FAJSP), FJSP with Sequence-Dependent Setup Times (FJSPSDST), and the online FJSP (with online job arrivals). Our primary goal is to provide a centralized hub for researchers, practitioners, and enthusiasts interested in tackling machine scheduling challenges.

Topics in Mixed Integer Programming and Nonconvex Optimization

Stream: MINLP

Invited session

Chair: [Jan Kronqvist](#)

1 - Distance geometry without the graph*Leo Liberti*

The Distance Geometry Problem (DGP) is as follows: draw a weighted graph in a K -dimensional Euclidean space (K given) so that vertices are points and edges are segments with the same length as their weights. In many applications the input is not quite a graph, but simply a list of distance values without their adjacencies. Thus, the assignment of distance values to graph edges must be carried out concurrently to the realization in the K -dimensional space. This is known as the unsigned DGP (uDGP). There is a natural MINLP formulation for the uDGP, which is very hard to solve even for tiny instances. We present alternative formulations as well as relaxations, restrictions, and other approximating reformulations.

2 - Optimization over trained graph neural networks: mixed-integer formulations, symmetry breaking, and optimal molecular design*Shiqiang Zhang*

Optimization over trained machine learning models has applications including verification, minimizing neural acquisition functions, and integrating a trained surrogate into a larger decision-making problem. We formulate and solve optimization problems constrained by trained graph neural networks (GNNs). For the classical GNN architectures considered in this talk, optimizing over a GNN with a fixed graph is equivalent to optimizing over a dense neural network. Thus, we study the case where the input graph is not fixed, implying that each edge is a decision variable, and develop two mixed-integer optimization formulations. To circumvent the symmetry issue caused by graph isomorphism, we propose two types of symmetry-breaking constraints, and provide a proof that adding these constraints will not remove all symmetric solutions. As a byproduct, a graph indexing algorithm is constructed to yield an indexing satisfying these constraints. To test our symmetry-breaking strategies and optimization formulations, we consider an application in optimal molecular design.

3 - Optimization-based algorithm for robustness enhancement of neural networks*Shudian Zhao, Jan Kronqvist*

This talk introduces an optimisation-based method for generating robust neural networks against adversarial attacks for image classifications. Instead of using large training data and heaving computing expense in classic training process, the proposed method only requires a small size of adversarial dataset in each outer iteration to improve the robustness a model trained with default settings. This algorithm includes two levels of updating. In the inner iteration, we add cuts to improve the linear approximation for the nonlinear constraints regarding the adversary behaviour and level of loss function. Then, to balance the performance of the model on both clean dataset and the adversarial dataset, we select the Pareto set by line search and update the model with a weighted objective function. In the outer iteration, we generate new adversarial data and repeat the same process until stopping criteria are satisfied. This talk concludes with numerical results with CNN and ResNet models.

4 - Solving large-scale ACOF problems*Matías Villagra, Daniel Bienstock*

The ACOF problem is a notoriously difficult nonconvex optimization problem arising in the operation of power grids. To date, all numerically effective relaxations – that is to say, both accurate and practicable, at scale – require second-order constraints. However, solvers have considerable difficulty tackling such constraints. In this talk, we will describe an outer approximation linear cut scheme that yields relaxations which are both tight and can be solved quickly and robustly. Additionally, we will describe a warm-start scheme that further improves on performance. Finally, we will present a theoretical justification for, both, the success of the SOCP relaxations and their outer approximations. Joint work with Matías Villagra (PhD student, Columbia University).

Advancements of OR-analytics in statistics, machine learning and data science 12

Stream: Advancements of OR-analytics in statistics, machine learning and data science

*Invited session*Chair: *Antonio Mauttone*Chair: *Gerhard-Wilhelm Weber***1 - Spatial analysis techniques for diagnosis situational of low birth weight at term in the state of São Paulo***Diego Eduardo Quagliato Scarelli Cava, Fernando Augusto Silva Marins, Elen Yanina Aguirre Rodríguez, Aneirson Silva, Elias Carlos Aguirre Rodríguez*

Low birth weight (LBW) is defined when newborns weigh less than 2,500 grams, and is considered at term when born at greater than or equal to 37 weeks of gestation. The incidence of LBW is considered a significant public health issue, closely associated with an increased risk of mortality and future morbidity. Furthermore, it is important to highlight that between 15% and 20% of children born worldwide have LBW. Therefore, to overcome this situation, researchers started to develop and use the Geographic Information System to identify areas at risk of health problems and create solutions for these places. Based on this, this study aimed to utilize spatial analysis to verify the distribution of LBW at term and identify high-risk areas within the 645 municipalities in the state of São Paulo from 2012 to 2021. Specifically, this study used the global Moran index to measure the degree of spatial association in the study area and the local Moran index to identify risk areas with high prevalence. The findings indicate potential presence of significant clusters of municipalities revealed by the global Moran index, which was substantiated by the local Moran index, highlighting three small clusters in the northern part of the state. This approach can assist health professionals and governmental bodies to formulate precise strategies and initiatives to mitigate LBW in these localities.

2 - Classification for natural language processing*Ioannis Tsiligkaridis*

Natural Language Processing (NLP) introduces computational representations of language with the word vectors as a potent approach. This work focuses on Sentiment Analysis for classifying the emotional intent of text. A variety of different types and layers of Neural Networks (NN) are used. A group of Deep Learning (DL) algorithms are used for classification starting from a Simple Dense Neural Network with Embedding layer (DNE) and continuing with the Convolutional Neural Network (CNN), the Long-Short Term Memory (LSTM), the LSTM with Dropdown (LSTMD), and the Ensemble model with LSTM and CNN (LSTM_CNN). Hyperparameters tuning for the NNs (i.e. learning rate, etc.) are also used. The use of hyper parameters will be able to boost the accuracy levels even higher. The grid search method is used for discovering the LSTM hyperparameters for better accuracy.

All approaches are tested for accuracy with Large Movie Review Dataset (IMDB). In DNE, misclassification of false positive and false negative is noticed. CNN, with one-dimensional sequence of words, improves DNE performance at classifying film reviews. The filter of the CNN layers obtained better results at learning short sequences. The LSTM surpasses LSTMD and LSTM_CNN.

3 - Spatio-temporal analysis of variable-density clusters in hot spot policing*Ben Moews*

The effective prevention of crime requires the availability of empirical data to optimise public resource utilisation and public safety outcomes. In this context, spatio-temporal incident reports can be used for newly developed variable-density cluster analysis approaches, for which empirical data collected over more than two decades in the City of Chicago is used. This provides insights into the evolution of crime

type ratios in the twenty-first century so far, with particularly notable effects from the recent COVID-19 pandemic due to shifts in space occupancy, with primary functions of city areas playing an important role. An analysis of spatial autocorrelations at different distances, as a methodology transfer from cosmology, demonstrates variations in incident uniformity between clusters and outlier areas, and highlights the need to question the currently wide-spread practice of cluster epicentre policing. One of the points the discussion focusses on is the role of criminology-oriented optimisation as an aspect of community operational research. This is particularly relevant when it comes to acknowledging risks due to known and unknown data biases, for example due to extraneous and temporally constrained events as well as impacts from spatially varying police-community relations.

4 - Investigating fairness in decisions involving ordinal classification - A COVID-19 case study

Edward Abel, Sajid Siraj

Ensuring fairness is important when evaluating decision support systems aiming for impartial decision outcomes and trust within those being affected. During the COVID-19 pandemic, numerous nations implemented tiered restrictions as a localized strategy to balance economic activities against restrictions of movement independently in different geographical areas. However, such approaches sparked debate on the fairness of these restriction decisions. We examine fairness concerning the UK government's allocation system for tiered restrictions which can be modelled as an ordinal classification problem. For this, we collected and integrated data from multiple official sources to investigate potential inconsistencies, such as comparing the North and the South of England. We explore if there is inconsistency, by first training an ordinal classification model using only data from one geographical area, then testing the model with data pertaining to another geographical area. This helps us identify and measure classification errors in terms of underestimates and/or overestimates of predicted values compared to the actual values. Such analysis can be useful for exploring ordinal classification problems, both for post-hoc analysis of past decisions, and for providing transparency as part of future decision dissemination. Our approach could be applied to other ordinal classification problems, to explore fairness within other domains.

Cutting and Packing 5 - related topics

Stream: Cutting and Packing (ESICUP)

Invited session

Chair: Rosephine Georgina Rakotonirainy

1 - Reducing shipping cost of packages by optimizing the bin set

Leon Binder, Johannes Kuchler, Michael Scholz

With the increasing number of parcels shipped worldwide, new ways to reduce the total shipping costs and CO2 emissions are actively searched. Past research primarily focused on finding bins that minimize the wasted volume for packing orders. Retailers, however, must decide about the bin sizes they will use for packing before any order will be packed. Having many bin sizes on stock will allow a retailer to more often select a bin with only some small wasted volume. Many bin sizes, on the other hand, increase costs for buying and storing bins as well as for selecting the best bin. To the best of our knowledge, the preliminary decision of what bin sizes a retailer should have on stock to minimize the total shipping cost is a yet unexplored optimization problem. We focus on the NP-hard problem of finding bin sizes (i.e., bin set) that minimize the costs for packing and transporting a given set of orders. More specifically, we i) define the problem of finding cost-minimal bin sets, ii) provide an adapted metaheuristic to identify good solutions to the defined problem and iii) discuss possible extensions of the provided solution.

2 - Exact and Heuristic Solution Approaches for Busy Time Minimization in Temporal Bin Packing

John Martinovic, Nico Strasdat

Given a set of jobs (or items), each of which is characterized by its resource demand and its lifespan, and a sufficiently large number of identical servers (or bins), the busy time minimization problem (BTMP) requires to find a feasible schedule (i.e., a jobs-to-servers assignment) having minimum overall power-on time. Although being linked to the field of temporal bin packing, BTMP represents an independent branch of research. Typically, such considerations (and generalizations of it) are very important in data center workload management to keep operational costs low. Hence, finding efficient and powerful solution techniques for BTMP is a relevant topic in cutting and packing, both from a theoretical and practical point of view. In this talk, we give an overview of heuristic and exact approaches for the problem under consideration and analyze their theoretical properties and computational behavior. As a first main contribution, we suggest a new best-cost based heuristic showing convincing results in a wide variety of numerical test. In terms of exact approaches, we propose some improvements for the ILP models from the literature and establish a new combinatorial flow-based formulation. Based on extensive numerical tests with differently-characterized benchmark sets, the flow model is shown (i) to improve the state-of-the-art approach for general instances, and (ii) to be competitive with a matching formulation tailored for a special case.

3 - The cutting stock problem with limited open stacks

Kelly Cristina Poldi, Gabriel Gazzinelli Guimaraes

A Cutting Stock Problem (CSP) consists of determining the best way in which a set of larger units (objects) should be cut in order to fulfill the demand for a set of smaller pieces (items) while minimizing a certain objective that can be, for instance, the number of objects or material waste. In industrial contexts, automatic cutting machines have a limited number of unloading stations and, thus, it is essential, in mathematical modeling, for accurate representation to consider these constraints added to the CSP. Such problem is known as the Cutting Stock with Limited Open Stacks Problem (CS-LOSP). In this research, we present an integer linear programming formulation for the CS-LOSP, and some computational experiments carried out on randomly generated instances.

Decentralized multi-energy markets

Stream: Energy Markets

Invited session

Chair: Russell McKenna

1 - Climate policy design in liberalized electricity markets with incomplete risk trading

Emil Dimanchev, Steven Gabriel, Filippo Pecci, Stein-Erik Fleten, Magnus Korpås

Climate policy makers aim to incentivize risk-averse firms to deploy large amounts of capital for clean electricity investments. This task is made harder by the limited availability of long-term contracts in electricity markets, which is known as the missing market problem. We study how this market failure affects optimal policy choices in power systems. To analyze optimal policy, we propose a bi-level programming approach that endogenizes policy decisions. Our model combines an "upper level" policy optimization problem and a "lower-level" generation expansion problem. The lower-level problem features risk-averse investors making decisions under demand and fuel price uncertainty as well as optimal power system dispatch. While bi-level programming imposes a computational burden, our formulation partly alleviates this problem. We are able to solve our model for a power systems featuring both variable renewables and energy storage with

time-linking constraints. We use this model to study the optimal design of several common climate policies including renewable portfolio standards, investment tax credits, and carbon pricing. Preliminary results show that optimal climate policy instruments are more stringent in power systems subject to the missing market problem than in systems with complete markets. We also find that missing long-term markets can make renewable portfolio standards more cost-effective than carbon pricing in some cases.

2 - Delivering Reliable Reserve Commitments from Intermittent Electricity Resources

Anil Kaya, Yashar Ghiassi-Farrokhfal, Steffen Rebennack, Mohammad Reza Hesamzadeh, Kai Pan, Derek Bunn

The expansion of renewable energy generation increases the need for short-term reserve facilities to compensate for their short-term variations. This makes reserve markets increasingly profitable and attractive for renewable energy producers (REPs), who are facing diminishing subsidies and returns. We study this problem by formulating the operation of a profit-maximizing REP, with and without storage, providing reserve services as a multi-stage stochastic integer program, separately with the support of discrete (D-ID) or continuous (C-ID) markets. We combine the Benders decomposition and stochastic dual dynamic programming algorithm (SDDP) to solve the problem efficiently. Our analysis of real data from the German market provides interesting insights into REPs' participation in short-term reserve markets.

3 - Market effects of Power-to-Gas technologies and their role under future gas supply shocks using a coupled electricity-gas-hydrogen market model

Yi Wan, Tom Kober, Russell McKenna, Martin Densing

Power-to-Gas (P2G), by converting surplus electricity to hydrogen using electrolyzers, will be a crucial component in the future low-carbon energy system. This study investigates the market impacts of large-scale P2G deployment, with a specific focus on electrolyzers and hydrogen storage, under a stringent climate scenario. We develop a game-theoretic equilibrium model of coupled day-ahead electricity, natural gas, and hydrogen markets for the Central Western Europe region. One novelty of this model is that we consider multiple hydrogen supply pathways, including national imports, elastic hourly hydrogen demand, and external costs of hydrogen blending in the representation of the (potential) wholesale hydrogen market. Besides lowering hydrogen market prices and increasing electricity market prices, electrolyzers may also increase electricity price volatility due to overlapping peak-load periods for electricity and hydrogen. The analysis of hydrogen storage highlights its role in mitigating general market volatility, albeit with only modest impacts on electricity markets, which indicates its limited potential to provide flexibility to the electricity market. Additionally, hydrogen storage may increase natural gas and hydrogen prices through its interaction with Steam Methane Reforming. This study contributes to the existing literature by providing insights for the effects of P2G on future energy markets in terms of intricate market dynamics and interactions induced by P2G.

4 - Large prosumers under capacity constraints: Market power effects of vertical integration and of storage

Martin Densing, Yi Wan, Russell McKenna

With the advent of batteries and P2X technologies, energy producers can also participate as consumers on energy markets, which increases the flexibility of such prosumers. We consider a single time-step market equilibrium where a large player is an integrated producer and consumer under capacity constraints. The capacity constraints are relevant for emerging consumer-side technologies, such as limited electrolyzer capacity. We use conjectural variations to model different levels of market power, and we solve the model analytically. Under market power, we compare the equilibrium solution with the one for a separated producer and consumer. We calculate corresponding production and consumption equilibrium amounts, prices, and social welfare. The main finding is that the social welfare change of vertical integration is ambiguous and depends on the parameters, for example the limited capacity of the consumption technology. Using the same analytical

method, we consider also a symmetric two time-step duopoly of capacitated storage and production under market power. Also in this case, we show how the equilibrium solution in terms of prices and storage amounts depends on parameters, for example the intensity of market power measured by the conjectural variation parameter. The findings may be used in energy-policy support to identify different cases for de-bundling energy technology assets.

Tuesday, 8:30-10:00 - Room: 11 (building: 116)

Radiotherapy and chemotherapy planning

Stream: OR in Health Services (ORAHS)

Invited session

Chair: Anders Forsgren

1 - Outpatient Chemotherapy Planning at Hacettepe Oncology Hospital: A Mixed-Integer Linear Programming Model

Gunsu Dagistanli, Meral Azizoglu

With the rising need for chemotherapy treatment exceeding the limited capacities of oncology clinics and hospitals efficient planning becomes crucial. For that, first stage is allocating patients to treatment days within the constraints of their treatment plans and hospital schedules. Second stage is preparing the daily appointment schedules of patients to maximize resource utilization and patient satisfaction considering nurse, chair, and other constraints. Based on the observations at Hacettepe Oncology Hospital in Ankara, we present a compact deterministic Mixed-Integer Linear Programming (MILP) model to address the first stage, known as the Outpatient Chemotherapy Planning (OCP) problem. The model accommodates multi objectives to comply the hospital policies and decision maker's goals. We find that for any selected objective, the solutions returned by our model outweigh the solutions currently implemented.

2 - A stochastic programming approach for chemotherapy planning

Melih Celik, Gunsu Dagistanli, Serhat Gül

Cancer is one of the most prevalent causes of death worldwide, second only to heart disease. Chemotherapy is the most widely used approach to treat cancer patients. There are many challenges for planning of chemotherapy appointments in oncology clinics, including the limited capacity of clinics and the uncertainty of the duration of treatment. For this end, an effective planning of chemotherapy schedules is vitally important.

In this study, we consider the problem of chemotherapy planning, where patients are assigned to days in the planning horizon according to their treatment frequency. Due to the uncertainty of durations, we model the problem as a two-stage stochastic program, with an objective that minimizes a combination of earliness and tardiness of appointment days, as well as idle time and overtime of chemotherapy chairs. As realistically sized instances of the problem are impossible to be solved by commercial solvers, we propose a scenario reduction-based heuristic approach that relies on k-medoids clustering to find the representative scenarios. We test the performance of our approach on a dataset from a chemotherapy clinic and derive managerial insights.

3 - Fuzzy optimization in beam Intensity Modulated Radiotherapy Treatment

Nicole Cristina Cassimiro de Oliveira, Aurelio Oliveira

Cancer is one of the main public health problems worldwide. Most cancer patients are treated with radiation. This treatment uses a source of ionizing radiation that destroys the tumor cells, in which it is possible to vary the intensity of the radiation fluence and the radiation beam can be shaped in such a way to radiate only around the tumor. Computed tomography scans are performed in order to define the target volumes and organs at risk, and then define the patient's treatment

plan, in which sufficient amounts of dose are prescribed for the tumor to cure, while minimizing the inevitable dose to the other regions. The prescription is normally made by the oncologist, which may be associated with uncertainties. Therefore, the dosage values are considered as fuzzy numbers. In this context, the dose distribution problem in radiotherapy planning translates into a fuzzy optimization problem in which mathematical programming techniques are used for the solution. Fuzzy constraints are mathematically translated by the surprise approach. The proposed methodology was applied in several cases of cancer using the TROTS database. The results obtained are compared by means of Dose-Volume Histograms and contour graphs and dose surface. In conclusion, the approach using fuzzy numbers produced viable treatment plans, inferring that the model is an important tool in decision-making in the planning of radiotherapy treatment.

4 - Motion-adaptive optimization for proton therapy with pencil beam scanning

Ivar Bengtsson, Anders Forsgren, Albin Fredriksson

Pencil beam scanning (PBS) is an advanced technique for treating cancer with proton radiation. It can deliver radiation with great precision, allowing the tumor to be targeted with less harm to healthy tissue. However, the precision comes with a large sensitivity to uncertainty of the patient's position and anatomy. Whilst robust optimization has proven successful in managing positional uncertainty in PBS treatments, treatment of motion-subjected tumors due to variational anatomy, such as those in the lungs, may benefit from a motion-adaptive treatment planning approach.

In this work, we build on previous attempts to explicitly plan with respect to the respiratory patterns of lung patients, as well as motion-adaptive optimization proposed for photon treatments, to propose a motion-adaptive control strategy for PBS. During the delivery of the treatment, the patient's breathing motion is tracked and predicted into the future. The predicted motion is then used to re-optimize the treatment over a receding horizon.

We show that the motion-adaptive strategy is superior to robust optimization in terms of both consistently treating the target with sufficient radiation and sparing nearby healthy tissue. Although much work remains to demonstrate the feasibility of implementing the proposed strategy in real-time, our results demonstrate the benefits of successfully implementing a motion-adaptive strategy, further realizing the precision advantage of proton therapy with PBS.

portfolio generation techniques. The results of the experiment demonstrate that path dependence can occur in policy generation. We report thinking patterns of subjects which relate to biases and heuristics.

2 - Pedagogy and prescriptive analytics

Jeffrey Keisler

Operations research involves mathematical modeling and analytic techniques. Some people learn modeling and then analytics, some learn the other way around, and some learn them simultaneously. Most modern textbooks seem to teach them together and center the modeling. Are there problems with that? I will explain why I think so. Can we do better? I will discuss how I think we can.

3 - Behavioral Decision Analysis

Gilberto Montibeller, Florian Federspiel, Matthias Seifert

This presentation lays out a foundation and taxonomy for Behavioral Decision Analysis, which can unify this work across various domains. Traditional research in the domain of Decision Analysis has focused on the design and application of logically consistent tools to support decision-makers during the process of structuring problem complexity, modeling uncertainty, generating predictions, eliciting preferences, and, ultimately, making better decisions. Two commonly held assumptions are that the decision maker's cognitive belief system is fully accessible and that this system can be understood and formalized by trained analysts. However, in past years, an active line of research has emerged studying instances in which such assumptions may not hold. We aim to unite this community under the common theme of Behavioral Decision Analysis. The taxonomy we suggest categorizes research based on task focus (prediction or decision) and behavioral level (individual or group). Two theoretical lenses that lie at the interface between (1) normative and descriptive research, and (2) normative and prescriptive research are introduced. We then proceed to highlight representative works across the two lenses focused on individual and group-level decision-making.

4 - Local knowledge and operational performance: Evidence from a digitized setting

Marijn Verschelde, Changyu Men, Maud Van den Broeke, Bart Roets

In digital control rooms, controllers' experience significantly impacts their performance. They accumulate expertise through repetition, termed local knowledge, given the stable and repetitive nature of their tasks. Alternatively, they broaden their skills by working across various workstations, termed neighbor knowledge. Our study investigates the role and impact of these types of knowledge on operational performance, and examines the portability of neighbor knowledge within digital control room settings. For this purpose, leveraging a purposefully built comprehensive dataset from a major European rail system operator, we analyze how workstation-based and train-based experiences influence controllers' operational performance, measured by train delay. Our findings reveal that accumulated work at the same workstation improves operational performance, underscoring the importance of local knowledge. Further, when focusing on operational performance regarding passenger trains, we observe higher performance for controllers with more experience in passenger trains, but also lower performance for controllers with more experience in freight trains, indicating potential drawbacks of neighbor knowledge on operational performance.

1 - Generating Policy Alternatives for Decision Making: A Process Model, Behavioural Issues, and an Experiment

Raimo P. Hämäläinen, Tuomas Lahtinen, Kai Virtanen

The generation of alternative policies is essential in complex decision tasks with multiple interests and stakeholders. A diverse set of policies is typically desirable to cover the range of options and objectives. Decision modelling literature has often assumed that clearly defined decision alternatives are readily available. This is not a realistic assumption in practice. We present a structured process model for the generation of policy alternatives in settings that include non-quantifiable elements and where portfolio optimisation approaches are not applicable. Behavioural issues and path dependence as well as heuristics and biases which can occur during the process are discussed. The behavioural experiment compares policy alternatives obtained by using two different

1 - Conventional or organic cattle farming? Trade-offs and optimal gross margin analysis

Mario Guajardo, Rasmus Bang, Leif-Jarle Asheim, Ola Flaten, Bjørn Gunnar Hansen, Jon Kristian Sommerseth

Interest for organic products and concerns regarding sustainable practices raise an important question for farmers: should they run their farms conventionally or organically? We address this question by means of a mathematical programming model tailored to Norwegian cattle farms. The model aims to optimize gross margin, subject to government support stipulations outlined in the Norwegian agricultural agreement and a number of other features. A computational study allows us to assess the economic performance of different farm settings and the trade-offs between crop yield, livestock capacity, organic premiums, and government payments. We derive some insights into the conditions when organic outperforms conventional systems, and vice versa. These hold significant relevance not only to farmers, but also to farm advisors and policy makers.

2 - Managing Hog Farm Operations under Uncertainty: Inventory and Selling Strategies

Panos Kouvelis

Problem Definition: We study the finishing stage (weeks 23-26 in the pig's life) planning problem of a pork producer who gets to see how market-ready hogs he has available at the beginning of each week for sale and the current market prices. Then, he must decide how many hogs to sell through to a meatpacker and on the open market. The producer has a contract to deliver a fixed quantity to the meatpacker each week according to a predetermined price formula that depends on commodity indices. He pays a penalty if he fails to deliver. The numbers of hogs that become market-ready every week, all costs, and all prices are stochastic. **Methodology:** We use a dynamic programming approach (optimal policy, a one period look ahead approximation). **Results:** We show there are two types of thresholds in optimally making decision switches (holding to contract fulfilling, holding to spot selling), each one specific to the under-weight and the regular-weight hogs. The thresholds are sensitive to the number of available hogs and prices and not straightforward to derive. An approximate dynamic program preserves the optimal policy structure and offers a practical solution approach.

3 - Comparative Study of Genetic and Differential Evolution Algorithms for Pareto Front Approximation in Dairy Feed Optimization

Gastón Nottle, Pablo Chilibroste, Martin Pedemonte, Hector Cancela

Evolutionary algorithms have emerged as potent solutions for addressing multi-objective optimization challenges across various practical scenarios. This study introduces a multi-objective dairy feed resource allocation optimization model and conducts a performance analysis of four methods to approximate the Pareto front; two genetic algorithms (GA: NSGA-II, SPEA-2) and two differential evolution algorithms (GDE-3, a variant of Pareto-based DE). Experiments utilizing real-world data were performed to evaluate the algorithms based on criteria such as execution times, Pareto front solutions, and performance indicator values, at the same time looking for the best parametric combinations for each algorithm. The results showed significant differences among the algorithms, both in their proficiency to approximate the Pareto front and in their execution times. SPEA-2 demonstrated superior results in terms of convergence, diversity, and cardinality, but suffered prolonged execution times. Future research could address this issue, combining SPEA-2 with other algorithms for efficient Pareto front approximations. Regarding the parametric combinations, significant differences were observed. For both GA, the importance of using a low value in the mutation probability is highlighted. For the GDE-3, a low value in the population size (N) and a high value in the crossover probability (CR) stand out. Finally, for the Pareto-based DE, higher values for N and CR gave better results.

4 - Maximizing profits by performing optimal marketing decisions in pig fattening farms

Pol Llagostera Blasco, Yun Bao, Lluís Pla

In today's highly industrialized and specialized pig production landscape, efficient decision-making is essential to navigate the complexities and maximize benefits. This study investigated the delivery of fattening pigs from farms to slaughterhouses, considering diverse growth patterns. An optimal marketing strategy is developed to maximise profits by adopting an all-in, all-out management approach. The research utilized the K-means algorithm to categorize actual growth data of fattening pigs into three clusters, each analyzed using the Gompertz animal growth model to assess growth rate, acceleration, and relative growth rate. Subsequently, a simulation of a fattening farm was conducted using a mixed integer linear programming (MILP) model to evaluate various parameters and develop optimal marketing strategies. These strategies, oriented for pig delivery schedules, cost analysis, and profitability assessment, were designed without needing individual control and weight measurement of fattening pigs. Sensitivity analyses were performed on key production factors affecting profitability, such as pig transaction price, feed price, and pig mortality during fattening, leading to the development of marketing strategies for each scenario.

OR Innovations in Policy Making - B

Stream: Soft OR and Problem Structuring Methods
Invited session

Chair: *Ine Steenmans*

Chair: *Irene Pluchinotta*

1 - Reflections on the Opportunities to Innovate Policy and using Problem Structuring Methods to Transform UK Public Sector Organisations

Martin Parr, Sophie Jackson, Adam Townsend

In the UK our public sector services are described as being delivered efficiently. Each project will have been funded based on needs, but at a macroeconomic level there is great opportunity to make improvements. So, why don't we make these changes? In part because it is difficult and the benefits won't be seen by the people who deliver the change. There is also no enduring structure and mandate within government to perform systemic change, although there is a structure for audit - highlighting more focus on risk than on the opportunity. Transformational change is possible and innovation is achievable. There are many opportunities to design policy to realise significant benefits, but we lack political will and appropriate control systems. A simple assessment can be obtained by comparing publicly available reports from key UK agencies such as The Metropolitan Police. It can easily be shown that there is a wide gap between the mission for each organisation and what they deliver. In considering systems level improvements, a project will be examined using methodologies such as Soft System Methodology (SSM) and the Viable System Model (VSM). This project will demonstrate that there is a need to develop policy using systems approaches. It will highlight the broader opportunities that may be possible, and that transformational change can be delivered for the UK government.

2 - Bronze, silver or gold? What's the added value of investing more in the analysis of medical technologies?

Alec Morton, Jamaica Briones, Pete Baker

Health Technology Assessment (HTA) is an applied discipline which involves providing support to decision makers about the cost-effectiveness and budget impact of medical technologies, with a view to informing decisions about reimbursement in a given country's health system. However, HTA is itself resource-intensive, and requires analytic skills which may be scarce, particularly in low and middle-income countries. In response, many countries have between explored with "adaptive" HTAs (aHTAs). The idea in an aHTA is for analysts in a target country to adapt the analysis and findings from HTAs from other countries, rather than undertaking HTA de novo. aHTA is thus less-resource intensive and quicker than full HTA, but at the expense of

lower contextual relevance. Drawing on systematic reviews and meta-analyses for a number of medical technologies, we run a series of simulations to quantify the financial and health loss of using aHTA for a typical country for a range of cost-effectiveness thresholds, and to explore the factors which drive high losses. This work is a staging post to building an optimisation model which would support a country to optimise its HTA budget across full and adaptive HTAs.

3 - Causal Loop Diagrams to address Nexus Biodiversity-Climate- Society governance challenges: insights from the gold mining in Ghana case study.

Raffaele Giordano, Stefania Santoro, Alessandro Pagano, Mohammed Armani

Designing policies for managing the Biodiversity Climate Society (BCS) Nexus claims for a better understanding of the complex and dynamic interactions among its components and an effective engagement of the stakeholders. To this aim, a Participatory System Dynamic Modeling (PSDM) framework was adopted in BIOTRAILS project (<https://biotrailsproject.eu/>). The PSDM framework is composed by several steps. This contribution focuses on the system mapping phase, whose scope is to map the interactions among the different elements of the BCS nexus, accounting for the stakeholders' understandings and diversity of problem framings. Causal Loop Diagram was used to formalize and analyse the stakeholders' knowledge. Methodological approaches based on Ambiguity Analysis and structural analysis were combined to identify the BCS nexus challenges and detect leverage points. Those elements will be, in a later stage of the project implementation, used to inform the stakeholders' involvement in Nexus policy design. The developed methodology was experimentally implemented to the gold mining in Ghana, to analyse their impacts on biodiversity losses and the dynamic evolution of the BCS nexus. A PSDM exercise was held in Kumasi to map the BCS Nexus system. The preliminary analysis of the obtained CLD show how stakeholders perceived gold mining impacts on the local environment and socio-economic context, and allowed us to start the process for the Nexus policy design.

4 - Challenges for systemic public policy evaluation

Ine Steenmans

In recent years there has been a renewed interest in 'systems-based', 'systemic', and 'analytics-driven' evaluation of public policy. This interest has been supported with contributions from systems, policy, and evaluation sciences communities (see Reynolds et al. 2016; OECD 2019; Blomkamp 2022; GO-Science 2022). Often the dissemination and learning from these contributions remain largely focused within these disciplines. I argue the resulting disconnect between related work challenges OR researchers and practitioners in identifying where they can meaningfully contribute to address current needs.

This paper aims to support OR contributions to future innovations in public policy evaluation by presenting a review of the current state of knowledge and practice in three parts. Three questions are used to explore OR's relationship to policy evaluation:

1. What makes an evaluation 'systemic'? 2. What challenges are currently faced in systemic policy evaluation? 3. How is and can the field of OR contribute to resolving these challenges?

Enhanced statistical methods for energy challenges

Stream: Energy Markets
Invited session

Chair: Reinhard Madlener

1 - Algorithm-Enhanced Fuel Poverty Prediction Using Household Characteristics, Socio-Economic Factors, and Clustering Analysis

Reinhard Madlener, Rahil Dejkam

This paper contributes to the literature on predicting fuel poverty risk by applying clustering analysis to identify fuel-poor households. The study develops a novel approach to clustering-based XGBoost model by integrating data from a representative household survey in the UK (N=11'974). The unobserved heterogeneity in fuel poverty households survey hides certain relationships between the contributory features in survey and fuel poverty. This study explores the application of the k-prototypes clustering method to group households into heterogeneous clusters. The study segments the entire dataset into three clusters. Four XGBoost models were developed and applied to the entire dataset and each cluster to predict fuel poverty in households. The list of input features includes housing characteristics, socio economic features, and energy-cost variables. Additionally, for analyzing all features the shapley additive explanations (SHAP) method has applied, showing the different degrees of effects of each feature on fuel poverty in the entire dataset. The k-prototypes clustering-based XGBoost model is a promising approach to identifying the households at the risk of fuel poverty. Policymakers can gain new insights by identifying key socio-economic factors to alleviate fuel poverty.

2 - Do Oil Market Shocks Affect Financial Distress? Evidence from Firm-level Global Data

Mohammad Mahdi Mousavi

This paper investigates the impact of three oil price shocks, i.e. oil supply shock, oil aggregate and specific demand shocks, on firm-level distress using a dataset including 8,130 firms across 48 countries from 2002 to 2022. The study also analyzes the role of energy diversification in the relationship between oil-specific demand shock and firm distress. The paper finds that aggregated demand and specific demand shocks increase firm distress risk while supply shocks reduce such risk. Furthermore, the findings suggest that energy diversification mitigates the impact of specific demand shocks on firm distress. The paper also implements several robustness checks, and the results remain the same. Potential policy implications are also discussed.

3 - Enhanced electricity prices forecasting from spillovers among commodities

Giovanni Bonaccorsi

The deregulation of electricity markets has emphasized the importance of accurate daily electricity price forecasting (EPF) due to electricity's non-storability and the necessity for day-ahead bidding to align demand with production. Accurate EPF is crucial for utilities and consumers, enabling effective bidding strategies, adjusting consumption to benefit from lower prices, and allowing producers to manage generation assets more efficiently. The challenge in EPF arises from the complex dynamics of electricity prices, influenced by factors like weather conditions, business activity, and consumer habits, which introduce volatility, seasonality, and unexpected price surges. Despite the success of deep learning methods in the literature on EPF, recent global events such as the COVID-19 pandemic and the Russo-Ukrainian war have shown the need for more adaptable forecasting models. This paper proposes an adaptive Long short-term memory (LSTM) model that responds to external shocks by monitoring a disruption signal based on the spillover of shocks across different consumer categories. This approach aims to enhance the accuracy of EPF by accounting for both direct and indirect effects of external shocks on electricity prices, using a dynamic threshold to update the forecasting strategy based on observed systemic changes. We demonstrate the better forecast performance of our approach and provide an application with a model of energy storage arbitrage.

4 - Applying Data-Driven Robustness for Weather year uncertainty to generate Robust Energy Systems

Sebastian Kebrich

Limiting climate change demands an extensive expansion of variable renewable energy technologies. Capacity expansion models estimate the necessary installations of these technologies. However, a major challenge of energy systems based on these technologies are interannual weather fluctuations across weather years leading to uncertainties

in capacity expansion as well as operation to match supply and demand. The presented study investigates the 38 government districts of Germany using 40 years of weather data with hourly resolution to calculate energy systems able to supply energy in all cases. Based on computational experiments with weather data from multiple years, we identify critical dark lull-patterns in weather years. We showcase how such patterns can be incorporated into arbitrary reference years by manipulating time-series data. The developed methodology takes uncertainties in the capacity factor based on the weather data into account and weighs them relative to the demand. Large discrepancies between capacity factors and demand indicate time periods with potential gaps between supply and demand. The resulting energy systems based on this manipulated weather year are then taken as input for cross-validation to proof feasibility of the resulting systems. The results show that already the inclusion of only a few, well selected time periods leads to robust energy system models with minor optimality gap and can ultimately to a substantial decline in calculation time.

Location planning in healthcare

Stream: OR in Health Services (ORAHs)

Invited session

Chair: [María Merino](#)

1 - A Hierarchical Compromise Model and Matheuristic Algorithm for Stochastic Location-Allocation in Healthcare

María Merino, Imanol Gago-Carro, Unai Aldasoro, Dae-Jin Lee

In critical situations, the precision of emergency medical service (EMS) responses is of highest importance, as it can significantly impact patient outcomes. The effectiveness of EMS operations relies heavily on the strategic positioning and allocation of ambulances. This study addresses the ambulance location-allocation challenge in the Basque Country (Spain), where a fleet of 90 ambulances, including both Basic and Advanced Life Support resources, serves a population exceeding 2 million residents.

To tackle this issue, we leverage historical data and use a Box-Cox Cole and Green distribution to forecast response times. We propose a two-stage stochastic mixed 0-1 linear programming model aimed at optimizing the primary objective of maximizing expected coverage. Additionally, the model accounts for various secondary objectives, including minimizing average response time and incorporating risk aversion measures such as Conditional-Value-at-Risk, within a hierarchical compromise framework.

Due to the computational complexities inherent in this model, we introduce a novel matheuristic algorithm that combines primal decomposition and machine learning techniques. Computational experiments on medium and large-scale instances exhibits promising performance in efficiently addressing the intricate EMS optimization problem. This research contributes to enhancing the effectiveness and responsiveness of EMSs, leading to improved patient care during critical emergencies.

2 - Improving the location and allocation of healthcare resources

Marcelo de Souza, Tailini Schultz, Lucas Pietro Biasi Rayzer

The appropriate location of healthcare resources and a proper allocation of patients are essential to ensure access to healthcare for as many people as possible. Examples of healthcare resources include examination and treatment equipment, and healthcare facilities, such as emergency centers. We propose an integer programming formulation for the location-allocation of healthcare resources based on the p-median location problem with additional constraints. We aim to minimize the average distance between patients and resources. Besides that, we present

an iterated greedy heuristic to solve large instances. We implement different construction and destruction procedures, restart and acceptance strategies, and also a local search method to improve solutions. Based on these components, we build an algorithm framework capable of generating different versions of iterated greedy heuristics. We evaluate both the exact and heuristic approaches to real-world instances of location and allocation of examination equipment (e.g. mammography units). We use a parameter configurator to automatically search for the best iterated greedy heuristic to solve these instances, producing high-performing algorithms. The heuristic produces near-optimal solutions while solving larger instances that cannot be solved exactly in a reasonable time. Besides that, the proposed approaches can support decisions in healthcare, allowing better use of available resources and improving people's access to healthcare.

3 - Mathematical Models for New Hemodialysis Center Location Determination and Patient Scheduling

Gerçek Budak, Gökçe Sabriye Horuk, Berfin Osedya Menlik, Aleyna Ağırman

Location selection and assignment problems, which are of great importance in healthcare systems, are strategic decision problems. In location selection, topics such as the capacity of the sectors, the market area where the sector is located, the performance of the system and efficiency affect the decision maker's choice. This study initializes to determine the location of the service center where the most preferred hemodialysis treatment is going to be offered in the treatment of Chronic Renal Failure (CRF), which is increasing rapidly, and on the assignment of patients to hemodialysis centers. Decision problems have been identified by different decision makers regarding CRF, which has morbidity and mortality values. Among the decision problems listed from the perspective of different decision makers, the mathematical model proposal for the new hemodialysis location determination determined as the subject of the study. In the problem, it is aimed to optimize service access to hemodialysis patients with the hemodialysis center planned to be opened by determining the area where hemodialysis treatment is most needed with the land allocation model. The aim of the study was to provide hemodialysis services at a minimum distance with different variations to hemodialysis patients in Ankara, Turkey which was selected as the pilot region. Four different objective functions are designed as the decision maker may have different preferences.

4 - Multiobjective robust optimization approaches for personalized medicine supply chain network design under failure rate uncertainty

Meng Wan, Songsong Liu, Richard Allmendinger

Nowadays, the development and practice of personalized medicine become strategically important. It focuses on individual patient needs and conditions, and due to the shelf life of personalized medicine, it has high requirements on temperature in production and transportation. Designing a stable personalized medicine supply chain network to efficiently complete the manufacturing and delivery of drugs is crucial to reduce supply chain costs and improve overall efficiency to promote positive industry development. A multi-period, multiobjective production and distribution network of personalized medical supply chain is established in this paper, considering distribution, manufacturing, logistics, time and logic constraints, to minimize cost and time and maximize demand coverage. With the influence of manufacturing failure rate as an uncertainty factor, the robust optimization method is used to deal with the uncertainties. In this paper, two clustering-based decomposition methods are proposed as the solution approaches, which are shown to solve models more efficiently than the proposed MILP model. Monte Carlo simulation is used to validate the performance the robust optimization approaches. Finally, the proposed model is extended to consider the fairness on waiting time among patients. The research outcomes could help to improve the operational efficiency of the personalized medicine supply chain and promote the sustainable development of the personalized medicine industry.

Tuesday, 8:30-10:00 - Room: 19 (building: 116)

Sports scheduling and optimization

Stream: OR in Sports

Invited session

Chair: [Dries Goossens](#)

1 - Optimisation for the Fantasy Football League

John Wilson, Mehmet Begen, Vineet Yagnik

Fantasy Premier League is a "play along" fantasy game that follows the real-world events of Premier League games. It allows Premier League fans to compete against each other in their knowledge of players and teams. Players can set their own teams of players in the Premier League, who then earn points through their real-world performance in the Premier League. There is a substantial body of research on American Football Fantasy Leagues. However, possibly during to the low scoring nature of soccer as compared to American football, the Fantasy Premier League has not drawn as much attention. We show how to incorporate publicly available information into frequentist and Bayesian statistical models that will be used in optimization model to select teams for each week.

2 - Strategies for surviving single elimination tournament knockout pools

John Trono

In a typical knockout (KO) pool, each entrant must select a winning team every week of the regular season. If they fail to do so, they no longer have a chance of winning that pool since that loss (or tie), by their chosen team, has removed them from the list of entrants who are still alive in that pool. Also, each entrant is allowed to select a team just once during that season. If this style of pool is extended to a single elimination tournament (SET), like Wimbledon, the World Cup, NCAA's March Madness, etc., then different players/teams must be taken in each round. Strategies for outlasting every other entrant in such a KO pool will be considered in this talk, and results from recent March Madness tournaments will also be examined. These strategies are quite different from those that may typically be utilized during a regular season KO pool as now one hopes to survive and advance past each round (where significantly fewer choices are available after each round, which is not the case in a weekly KO pool). Therefore, outlasting all other entrants (who have not already been knocked out) is much harder to achieve. (Many of these SET KO pools require 2 or more choices per round - at least until the semi-finals have been reached.)

3 - Scheduling Bolivia's First Division football season by integer programming

Gonzalo Zamorano, Guillermo Durán, Mario Guajardo, Denis Saure

In this talk we describe our work in scheduling the main professional football league of Bolivia. Following existing work in sports scheduling, we develop an integer programming approach for the season schedule in its two tournaments, the first one organized by groups and the second one, a double round robin scheme. In addition to the traditional problem of scheduling games to rounds, we also schedule the games to specific dates and time slots within each round. Also, besides usual considerations such as league format, game broadcasting, and international tournament calendars, an important aspect of this league is the geographical location of the teams, which are spread around regions with extreme differences in altitude. Our work has been implemented in practice to schedule the 2024 season of the league. This is the fourth soccer league in South America (Chile, Argentina, Ecuador, Bolivia) programmed by the group of authors of this work.

4 - Beyond leagues: a single incomplete round-robin tournament for multi-league sports timetabling

Dries Goossens, Miao Li, David Van Bulck

Most sports associations regularly face the problem of determining and scheduling games for a huge number of non-professional (youth) teams. During planning, it is key to respect venue capacities and minimize travel distance. A classic approach is to split up teams over leagues, and then having each league play a round robin tournament. In a round robin tournament, each team competes against every other team in the tournament an equal number of times. In this talk, we propose an alternative approach, organizing a single yet incomplete round robin tournament. In this format, each team plays the same number of games, but teams are not required to face the same opponents. We exploit this flexibility to reduce the total travel distance and venue capacity conflicts. Besides integer programming models, we provide theoretical results and an iterative two-phase decomposition heuristic. This heuristic first determines the home-away status of teams based on the venue capacity of clubs, and next selects suitable opponents while minimizing travel distances. Extensive experiments using real-life benchmark instances from the literature confirm the advantage of an incomplete round robin tournament compared to the classic multi-league approach and validate the effectiveness of the proposed heuristic.

Optimization of sustainable urban mobility

Stream: Sustainable Cities

Invited session

Chair: [Luciano Costa](#)

1 - Greedy heuristic for solving real size instances of the bicycle network improvement problem

Emmanuel Neron, Felix Repousseau, Tifenn Rault, Matteo Doyen

We are interested in the bicycle network improvement problem. Let a set of paths obtained from GPS traces represent the cyclist's path on a graph. This graph consists of nodes, i.e. intersections, and arcs, i.e. roads with or without bicycle facilities. Thus, for each arc, we get the danger as a function of its length, the bicycle facilities, and the maximum car speed. A user's cost is given by the cost of his best path, while the cost of an arc is given by a linear combination of its distance and its danger, depending on his own preference. The user's preference between danger and distance is also given. We focus on where cycling facilities must be placed to minimize the sum of users' costs. Each time a cycling facility is decided, it costs money (depending on the length of the arc to be improved), and the total budget is limited. This problem is NP-hard. We present a greedy heuristic. At each step of the algorithm, we evaluate for each arc the impact on each user of upgrading that arc. We choose the arc that maximizes this impact on the sum of the users' costs. Using two Dijkstra algorithms (one forward, one backward) per user allows us to compute this impact efficiently. Moreover, this algorithm can be easily parallelized (the phase of computing the two Dijkstra algorithms per user) using multithreading. Some real instances (40 000 nodes and more than 20 km of plant proposal) can be treated in a few seconds on some classical desktop computer.

2 - OPTIDENS : A Mathematical Programming Approach for the 15-minute city model

Serigne Gueye, Cyrille Genre-Grandpierre, Jean-Christophe Mounier

The 15-minute city model proposes a redesign of the urban system to provide access to daily needs or destinations (work, food, health, education, culture and leisure) within a 15-minute walk, cycle or public transport journey. One of the main objectives is to reduce car dependency and its side effects. The 15-minute may be implemented by thinking a city as a possibility of choice leading to a Social Interaction Potential (SIP). That is the possibility of easily reaching numerous and

diverse people; a potential of jobs or any other amenities. The problem is that the high level of these potentials, which depend on density and transport speed, has been achieved for decades mainly thanks to the speed of the car. Cities are currently built on temporal proximity (by car) rather than physical proximity, which generates car dependency. In order to move towards a more sustainable mobility, it is imperative to return to more physical proximity, to a functioning based more on short distances, which is the idea of the 15-minute city. The question, then, is how to return to an urban functioning based on short distances without abandoning the essence of cities, in particular a high level of SIP. We have developed an optimization model, called OPTIDENS, which allows to find (if possible) the suitable location (or relocation) of any set activities in a city, in such way to respect a given SIP at the lowest travel speed. Some numerical results on data from real-life cities will be given.

3 - Optimizing the Determination of Criteria for Cyclists' Route Selection

Rafael Praxedes, Stefano Ardizzoni, Luca Consolini, Mattia Laurini, Marco Locatelli, Irene Saccani, Anand Subramanian

The promotion of sustainable transportation modes, such as cycling, has emerged as a crucial aspect of urban planning and design. The design of an efficient bicycle network is a complex optimization problem that requires analysis of different factors including infrastructure layout, connectivity, safety, and accessibility. However, before building the network, it is fundamental to understand the behavior of its users. The fastest routes are not always the preferred options for cyclists, who consider different criteria when choosing the best routes from their origin to their destination. Therefore, the aim of this study is to analyze the cyclists' choice behavior in the city of Parma, Italy. This analysis consists of defining a set of user profiles, where each profile corresponds to a combination of criteria used by the cyclist to choose a route, such as shortest time, safety, and connectivity. We proposed a bilevel formulation and developed a hybrid method to address this problem, which combines the solution of multiple shortest path problems with a heuristic method to determine the profiles. This approach takes advantage of solving the problem in a closed form by computing beforehand as many shortest path solutions as the number of profiles and then solving a simple quadratic programming problem. We validated our method using both randomly generated and real data collected from bicycle sharing companies in the city of Parma.

4 - Optimal design of an electric carsharing system under uncertain trip duration and energy consumption

Céline Gicquel, Mouna Kchaou-Boujelben

Electric carsharing systems allow individuals to borrow electric cars on a short-term basis for a rental rate charged by the time or the distance driven. These systems are seen as a promising way to both lower the CO₂ emissions linked to urban mobility and reduce urban congestion through a decrease in the number of privately owned cars parked in cities. We focus on the optimal long-term design of a station-based car-sharing system in which shared cars should be picked-up and dropped off by customers at stations. More precisely, we seek to determine the number of chargers to build in each station and the size of the vehicle fleet to deploy in the network. One major difficulty here is that to be practically relevant, the modelling of this strategic problem should be able to estimate the future revenue that one may get by operating the proposed system on a daily basis. Our model should thus consider operational decisions such as trip request acceptance, car dispatching to stations, intra-day car charging and relocation. Furthermore, in practice, uncertainties on the trip duration and energy consumption may prevent cars from being available when and where needed with a sufficient battery state of charge. To handle this difficulty, we first propose a new scenario-based two-stage stochastic programming approach. We then seek to assess the value of a stochastic solution by discussing numerical results carried out on randomly generated instances.

1 - Integrated Planning of Electricity and Gas Networks for the Energy Transition Using Stabilized Benders's Decomposition

Christian Perau

Integrating increasing capacities of renewable energy sources necessitates sector coupling. The coupling between the electricity and gas sectors is critical since they can be coupled bi-directionally via electrolyzers and gas turbines. Furthermore, the natural gas system must either be defossilized or the energy carrier must be switched to prevent greenhouse gas emissions. Hydrogen is expected to partially replace the currently used natural gas. Different infrastructure elements can be repurposed to transport hydrogen, which could reduce infrastructure costs significantly. Currently, the different systems are planned independently. However, planning the system using an integrated model might lead to significant cost reductions due to exploiting synergies between the systems. The integrated optimization could also enhance the system's reliability and efficiency. We propose utilizing stabilized Bender's decomposition to optimize integrated energy systems, including the electricity, natural gas, and hydrogen sectors. This approach improves performance by effectively decomposing the problem into smaller, more manageable subproblems. Integrating bundle methods improves the convergence of Bender's decomposition. We demonstrate the performance of stabilized Bender's decomposition within a case study of an IEEE system. The complex integrated energy system model can be solved close to optimality by adopting methodological advancements such as stabilized Bender's decomposition.

2 - On a Tractable Single-Level Reformulation of a Multi-level Model of the European Entry-Exit Gas Market with Market Power

Julia Grübel, Veronika Grimm, Martin Schmidt, Alexandra Schwartz, Ann-Kathrin Wiertz, Gregor Zöttl

We propose a framework that allows to quantitatively analyze the interplay of the different agents involved in gas trade and transport in the context of the European entry-exit system. While previous contributions focus on the case of perfectly competitive buyers and sellers of gas, our novel framework considers the mathematically more challenging case of a strategic and monopolistic gas seller. We present a multilevel framework that is suitable to capture the sequential nature of the decisions taken. We then derive sufficient conditions that allow for reformulating the challenging four-level model as a computationally tractable single-level reformulation. We prove the correctness of this reformulation and use it for solving several test instances to illustrate the applicability of our approach.

3 - The reorganization of the natural gas transport network in Belgium following the cessation of gas deliveries from the Netherlands.

Daniel De Wolf

The Belgian gas transport network is divided into two separate networks: the low calorific gas network from the Netherlands and the high calorific network with gas arriving from other producers. The Netherlands has announced the gradual cessation of the delivery of Dutch gas to Belgium. It is necessary to reorganize the transport of gas. Compared to the existing model for the Belgian network, two important changes must be modeled: on the one hand, the disappearance of the historic supplier will imply significant changes in gas flows in the single network merger of the two old ones. This involves possibly resizing of gas pipelines, reversing the direction of use of compression stations or creating new ones.

The other important change in the model is the objective function. Historically, a single company purchased the gas and transported it. Its main objective was therefore to minimize its gas purchasing costs. This no longer corresponds to the current situation where the commercial function is separated from the transport function. We take into account the new situation: namely the minimization of gas transport costs.

We present real data of the new Belgian network and the new formulation to provide a case study for all future developments in the field of gas network operations, an activity particularly subject to variations in recent years in Europe.

1 - Student Timetabling Optimisation for the Australian Defence Force

Katie Mortimer, Terry Caelli

Personnel in the Australian Defence Force must complete a number of training courses throughout their career. Currently, timetabling is performed manually across hundreds of courses and associated sessions, resulting in inefficient or incorrect timetables. To address this, we have created an optimisation algorithm to improve timetabling efficiency and administrative workloads. For this problem, there are a number of hard constraints, including: a maximum number of students per session, students cannot attend overlapping courses, and a number of fixed training pathways or course sequences. Soft constraints such as prioritisation of students is also important. In this domain efficiency is defined in terms of the total time delays in students being able to complete their training.

The algorithm uses a combination of Dynamic Programming (DP) and Genetic Algorithms (GA) to create optimal timetables where DP is initially used to find the optimal timetable for each student over course pathways and session options - which decrease as each timetable is generated over the student priority queue. The GA is then used to, where possible, improve upon these initial solutions by considering more efficient permutations and combinations of specific course and sessions over all the student DP solutions. The results showed a 45% increase in efficiency, reducing the average student delay by approximately half compared to the manual solution, and in a fraction of the time.

2 - Artillery Firing Shift with Two Registration Targets

Michael Bendersky

Firing shift is the shifting of artillery fire from one target (registration) to another by the application of corrections determined from the adjustment of the initial firing data for the first target to the second (application). In this paper, a shift method based on simultaneous firing at two different registration targets rather than a single one is introduced. A method is presented for using the observed data to explicitly solve for four major environmental parameters that affect ballistic trajectories and subsequently update them for the application mission. The distribution of the remaining errors is determined and compared with that of other correcting algorithms. Numerical examples show the potential of the proposed method.

1 - Optimizing Disaster Relief Logistics in Chile: A Location-Inventory-Routing Framework

Lorena Pradenas, Dagoberto Cifuentes, Víctor Parada

Chile's susceptibility to natural catastrophes, encompassing earthquakes, tsunamis, and volcanic activities, is exacerbated by climate change, resulting in heightened occurrences and increased severity of wildfires, floods, landslides, and droughts. Within this context, optimizing logistics planning and routing is critical to ensure timely aid delivery to affected communities. Our study introduces a novel routing model tailored to address unique geographical and disaster-related challenges faced in Chile. Unlike existing approaches, our model integrates comprehensive inventory control and distribution hub placement, optimizing relief supply routes in natural disasters. We propose a mixed integer linear programming (MILP) model to formulate a supply chain network strategically allocating distribution centers, regulating their inventories, and planning for ground and aerial transportation of relief goods. The efficacy of our proposed model is assessed through experimentation using real-world data sourced from various locations in Chile that have experienced natural disasters.

2 - Capacitated Mobile Facility Location Problem with Mobile Demand: Efficient Relief Aid Provision to En Route Refugees

Dilek Gunnec, Amirreza Pashapour, Sibel Salman, Eda Yücel

Forced displacement entails relief aid distribution efforts among en route refugees to alleviate their migration hardships. This study aims to assist humanitarian organizations in cost-efficiently optimizing logistics of mobile facilities to deliver relief aid to transiting refugees in a multi-period setting. The problem, referred to as the Capacitated Mobile Facility Location Problem with Mobile Demands (CMFLP-MD), involves refugee groups following specific paths and receiving aid at least once every fixed number of consecutive periods. The overall costs associated with capacitated mobile facilities are minimized. We formulate a mixed integer linear programming (MILP) model and propose two solution methods: an accelerated Benders decomposition approach and a matheuristic algorithm relying on an enhanced fix-and-optimize agenda. We evaluate our methodologies using realistic instances based on the 2018 Honduras migration crisis. Numerical results reveal that the accelerated Benders decomposition excels MILP with a 46% run time improvement on average while acquiring solutions at least as good as the MILP. Our matheuristic acquires high-quality solutions with a 2.4% average gap compared to best-incumbents rapidly. Sensitivity analysis highlights the managerial advantages of implementing CMFLP-MD solutions.

3 - The Stochastic Location-Routing Problem with Truck-Drone Tandem for Humanitarian Aid Delivery

Hannan Tureci Isik, Melih Celik, Ece Sancı

Timely response is crucial in humanitarian logistics to reduce suffering and loss. Network disruptions after a disaster, or due to unreliable networks, can cause prolonged travel times or isolate locations. These uncertainties necessitate a systematic approach to anticipate challenges in humanitarian logistics and ensure timely aid delivery. We propose a novel network design problem that strategically locates depots to enable efficient post-disaster deliveries. We incorporate the post-disaster uncertainties through stochastic travel times on the road network and formulate the resulting stochastic location-routing problem as a two-stage stochastic program. We explore the integration of drones with ground vehicles to overcome the network inaccessibility and long travel times on the road network to improve response times.

We focus on independent truck-drone deliveries from depots to transport lightweight aid bundles, such as medical supply kits, weather protection items, or communication tools. We develop a tailored heuristic based on variable neighbourhood search and compare its performance with CPLEX in small instances. We implement the heuristic in a case study of the Van Earthquake 2011, Türkiye. Through this implementation, we evaluate the value of the stochastic modelling approach and the tandem delivery model and perform sensitivity analysis. Our results show that the use of drones can significantly enhance delivery times by more than 50% in our case study.

4 - Disposal mechanism design for relief supply recycling in post-disaster humanitarian logistics

Anqi Zhu, Yu Fan, Xihui Wang

Relief supplies are crucial in response to a disaster. However, current studies focus on the raise, delivery and allocation of relief supplies during the process of disaster relief, and it remains uncertain that how to deal with the recyclable relief supplies after responding to a disaster. Motivated by the field investigation and interview, in this paper, we aim to design a disposal mechanism to help the local authority decide the optimal value level, which determines whether the relief supplies should be stored for future use or disposed through an auction. Furthermore, we consider whether the local authority can benefit more from processing (e.g., classification and cleaning) the relief items for auction. A case study based on the practical background in China has been conducted to prove the feasibility of our mechanism. The result shows that through our disposal mechanism, the local authority can achieve a balance between reducing the high inventory cost and avoiding potential waste of useful relief items, which gains more benefit and fits for the Sustainable Development Goals.

Optimization of energy storage systems

Stream: Energy Management

Invited session

Chair: [Emre Nadar](#)

1 - Pumped hydro energy storage: structural results and solution algorithms

Emre Nadar, Harun Avci, Ece Cigdem Karakoyun, Ayse Selin Kocaman, Parinaz Toufani

We study the energy generation and storage problem for a very general configuration of a pumped hydro energy storage (PHES) facility having two connected reservoirs fed by natural inflow. The operator decides in real-time how much water to pump or release in the PHES facility, thereby determining the amount of electricity to buy from or sell to the market. We model this problem as a Markov decision process under uncertainty in streamflow rate and electricity price. We prove the optimality of a state-dependent threshold policy under positive electricity prices: The state space can be partitioned into several disjoint domains, each associated with a different action type, such that it is optimal to bring the total amount of water in the PHES facility and the amount of water in the upper reservoir to a different pair of state-dependent target levels in each domain. Leveraging our structural results, we develop a policy-approximation algorithm as a heuristic solution method when the electricity price can be negative. This algorithm yields near-optimal solutions in our data-calibrated instances one order of magnitude faster than the standard dynamic programming algorithm. Modifying this algorithm by imposing partial-state-dependent target levels leads to up to 29 times faster solution times and reduces total cash flows by only 1.32% on average from optimal.

2 - Energy Storage System Design and Management for Renewable Supply and Demand

Gülin Yurter, Ayse Selin Kocaman, Emre Nadar

Renewable energy sources have gained prominence in reducing the dependency on fossil fuels and minimizing their negative environmental impacts. Considering renewables' uncertain and variable nature, it has become necessary to design and manage hybrid energy systems. We study the optimal design and management problem for hybrid energy systems involving a pumped hydro energy storage facility and a wind farm. We first develop two-stage stochastic programming models to find the optimal configuration and sizing decisions. We then utilize a Markov decision process model to find the optimal energy generation and storage decisions. Using real-life data and considering economic benefits, we investigate how hybrid systems can mitigate the negative effects of uncertainty in supply and demand.

3 - Operational benefit of transforming cascade hydropower stations into pumped hydro energy storage systems

Parinaz Toufani, Emre Nadar, Ayse Selin Kocaman

This study evaluates the potential benefit of retrofitting existing conventional cascade hydropower stations (CCHSs) with reversible turbines so as to operate them as pumped hydro energy storage (PHES) systems. We examine the energy generation and storage problem for a CCHS with two connected reservoirs that can be transformed into a PHES system in a market setting where the electricity price can be negative. We formulate this problem as a stochastic dynamic program (SDP) under uncertainty in the streamflow rate and electricity price. We analytically derive an upper bound on the profit improvement that can be obtained from the PHES transformation. We conduct numerical experiments with data-calibrated time series models and observe that the PHES system provides a greater benefit under more limited streamflow conditions or more frequently observed negative prices.

4 - Optimal operation of a residential smart grid with short-term and long-term storage

Eléa Prat, Pierre Pinson, Richard Lusby, Riwal Plougonven, Jordi Badosa, Philippe Drobinski

To enhance buildings' energy independence and carbon neutrality, technologies like energy storage and local renewables are increasingly deployed. Among these, long-term geothermal storage for residential buildings is emerging and poses new challenges in multi-timescale optimization. We investigate the operation of a novel residential smart grid, based on a real project. It integrates electricity and heat systems via a heat pump and includes short-term electricity storage, long-term thermal storage, photovoltaics, and solar thermal assets. While the operation is optimized daily, seasonal considerations are crucial, especially to ensure that the thermal storage fills during summer. The question then is how to account for long-term effects in the daily optimization. Our study relates to two key domains of operations research: inventory management and resource allocation. Utilizing a year-long real dataset, we explore different methods to guide the energy storage levels by day's end. These methods range from historical data-based thresholds to rolling-horizon strategies, assessing the impact of optimization window length. We also evaluate the relaxation of end-of-horizon constraints using penalties. We analyze the strengths and weaknesses of each method, acknowledging the challenge of unreliable long-term forecasts. These insights facilitate decision-making for residential energy systems and provide valuable implications for capacitated warehouse problems in other contexts.

1 - Incentivising-sharing-enabled optimal placement strategy on a reusable transport item rental platform

Min Guo, Hing Kai Chan, Xiang T. R. Kong

A rental platform offering customised reusable transport items (RTIs) grapples with placement challenges impacting RTI availability and usability. Notably, RTIs often stay idle in customer warehouses, adding no value. Thus, incentivising the business customers' sharing and optimising the platform placement decision are worth further research, but have not been well discussed in previous literature. Therefore, this study introduces an optimisation decision framework aimed at encouraging B2B sharing and refining RTI placement and customer incentives, innovatively using empirical and optimisation models. A quantitative model evaluates business customers' willingness to share (WTS) under varied incentive schemes and RTI needs. Incorporating WTS, we develop a bi-objective optimisation model with a large-scale heuristic algorithm to determine optimal RTI purchasing and sharing incentives pricing. Our real-case analysis illustrates that an RTI-sharing strategy reduces operational costs by 18.5% and boosts customer welfare, achieving a win-win scenario. Additionally, our findings suggest the platform's strategies on sharing incentives and resource procurement should adapt based on customer WTS preference, RTI reusability, and holding durations. This research could extend to similar rental networks or sharing platforms, underlining the significance of strategic resource placement and sharing incentives.

2 - From a linear supply chain to a circular economy: The impact of sustainable sourcing labeling regulations

Lena Silbermayr, Danja Sonntag, Martin Waitz

Across the clothing industry accounting for 60% of the world's textile waste, less than 1% of the used products undergo closed-loop recycling enabling the use for equal-value applications. This highlights the problem of a highly linear supply chain in the textile industry, where textiles are produced, used and mainly disposed of.

This paper contributes to the current debate on transforming the textile industry into a circular economy. Taking into account the challenges of a highly seasonal industry with high demand uncertainties, we combine inventory management practices to reduce waste with a systematic analysis of the economic and environmental impacts of different sustainable sourcing labeling regulations. In particular, we focus on three potential policies set by governmental regulators and their impact on the manufacturer's sourcing decision regarding traditional and chemically recycled feedstock. In the analysis, we incorporate the effect of the manufacturer's purchasing decisions and governmental regulations about sustainable sourcing labeling on consumer demand driven by consumer environmental awareness. We derive the manufacturer's optimal sourcing and production quantities and analyze their impact on economic and environmental key performance indicators.

3 - Do upcoming EU circular economy legislations require new OR applications?

Sonja Rosenberg, Frank Schultmann

Fostering and strengthening the circular economy (CE) with all of its dimensions is one objective of the European Union to reach its goal of becoming climate-neutral by the year 2050. Therefore, the EU has started with revision, extension, and the new development of circular economy regulation and guidelines. We provide a comprehensive discussion that shows how operation research methods can underline the goals of the upcoming regulations and serve as decision support for actions of circular economy shareholders on the European market. Therefore, we develop case studies based on different European regulations. The EU legislations under consideration include the EU battery regulation, the directive on common rules promoting the repair of goods and the Eco-design requirements for sustainable products. We investigate how legal CE innovations affect different supply chain problems in case studies. Legal CE innovations include, for instance, digital product passports or the obligatory usage of recycled content in

production. For each case study, we point out if the legal CE innovation is an emerging research field that needs to be investigated or if the OR community has picked up the problem.

4 - A review of the synergistic role of optimisation, game theory, and policy interventions in making the fashion industry circular

Marjan Olfati, Afshin Mansouri

Dealing with post-consumption clothing products is key to make the fashion industry circular. This will require effective reverse logistics to support the Re-x processes of the circular economy. The design of effective reverse logistics networks is a multifaceted task that need to cater for the different stakeholders and multiple decision criteria. This paper provides a systematic overview of the literature in the context of the fashion industry in three key areas: (i) reverse logistics, (ii) circular economy, and (iii) policy interventions. The focus of the first is optimisation and operations research models as well as game theory models. The second area looks into the application of the circular economy and sustainability. In the third area, the main policy interventions include extended producer responsibility (EPR), taxation, eco-labelling, and waste management. A comprehensive search was conducted on Web of Science. The managerial insights are proposed as follows: Designing operations research models assists decision-makers to optimise transportation, profit, waste, and location-allocation of facilities. Game theory models drive stakeholders to compete strategically, finding equilibrium in decision-making for resource allocation, costs, and pricing. Using game theory models can also exhort players (retailers, recyclers, charities, and customers) to collaborate, earning profit and fostering a sustainable supply chain, minimising waste and maximising resource reusing.

Invited session

Chair: Khakim Habibi

1 - Sustainable Group Traveling Purchaser Problem: Unlocking Value and Environmental Benefits with Bundle Discounts

Zahra Sadat Hassanpourjesri

The Traveling Purchaser Problem (TPP) has been a central focus in supply chain management, aiming to optimize the procurement process while minimizing total purchasing and transportation costs. We consider a new variant of TPP, one that incorporates shared vehicles among the purchasers and harnesses the power of bundle discount policy from suppliers. In our proposed structure, buyers can not only use the capacity of each other's vehicles but also integrate their demands, and by group purchasing receive their needed items through bundle discounts at the lowest price. In a typical bundle discount policy, a buyer might be reluctant to buy the whole bundle's items individually. Consequently, this study delves into the amalgamation of demands of different purchasers to harness the advantages of bundle discounts. Meanwhile, each bundle contains some environmentally friendly goods that determine its sustainability score. The innovation of this paper provides an opportunity for purchasers to obtain significant cost savings by engaging in group purchasing bundles with the highest sustainable scores. This allows them to procure eco-friendly products while simultaneously benefiting from discounted prices. We propose a tailored mathematical model for this new version of TPP, which we then solve using an approximated heuristic algorithm. The findings underscore the substantial role played by group purchasing strategies in cost mitigation and the enhancement of sustainable procurement.

2 - Vehicle Routing Problem with Backhauls: An Application with Electric Vehicles

Haluk Yapicioglu

In Vehicle Routing Problem with Backhauls (VRPB) is a special type of vehicle routing problem in an effort to reduce the overall cost of shipment from/to a depot. In VRPB, customers are divided into two categories as linehaul customers and backhaul customers. A vehicle that starts from depot first delivers goods to linehaul customers, then bring goods from backhaul customers to the depot on the way back. In this study, we tackle the VRPB problem with electric vehicles. Electric vehicles require special attention in route planning as they also require stops for charging. To this end, we developed a two-stage optimization procedure which constructs the routes for delivery and backhauls and determine the location of EV charging stations by taking into account both constructed routes and charging needs of the vehicles. The method is presented on an example dataset received from a manufacturing company located in Eskisehir, Türkiye.

3 - Sustainable Routing and Perishable Inventory Optimization under Demand Uncertainty for a 2- stage Divergent Supply Chain: A MILP-Based Hybrid Modelling Approach

Devansh Rai, Chandrasekharan Rajendran

In the dynamic landscape of perishable product management, efficient inventory optimization is crucial for minimizing waste and maximizing profitability. This research focuses on enhancing inventory optimization for perishable products in a 2-stage divergent supply chain involving a distributor and multiple retailers. The study proposes a novel approach that integrates sustainable inventory routing and inventory ordering policies to address challenges in inventory management. The model approach is a two-stage stochastic optimization problem with a multi-period perspective. The framework considers price-dependent demand, perishable product characteristics, back-ordering at the distributor, lost-sales at the retailers, demand uncertainty, age-based markdown pricing, and distributor-led inventory rationing. The research introduces a comprehensive policy and routing framework combining innovative inventory ordering policies and routing strategies. The proposed hybrid policy will be benchmarked against established inventory models, including (s,Q), (s,S), Haijema (s,S,q,Q), and other continuous review policies, all integrated with inventory routing. The new inventory policy can facilitate informed ordering decisions, preventing overstocking and understocking, thereby addressing real-world uncertainties and practical constraints in perishable product supply chains. Additionally, a heuristic method can be developed to provide efficient solutions within a limited timeframe.

4 - Bi-objective sustainable crowdshipping with multi types of occasional drivers

Khakim Habibi, Daniel Sanchez Pineda, Audrey Cerqueus, Alexandre Dolgui

Being competitive in last-mile delivery is a key factor for retailers, considering both cost and customer satisfaction. Crowdshipping addresses this by using ordinary people making deliveries on their habitual routes, being presented as a sustainable option. Yet, industrial initiatives have shown that it does not imply to be sustainable as compensation can attract more people, executing deliveries out of their normal routes. Our work introduces a crowdshipping problem optimizing both cost and CO2 emissions in a deterministic approach, referred to as the Bi-Objective Vehicle Routing Problem with Multi types of Occasional Drivers and Time Windows (BO-VRPMDTW). It generalizes the participation of Occasional Drivers (ODs) using different types of vehicles (fueled and non-fueled). The compensation policy defined assigns higher compensation to the non-fueled type. An epsilon constraint approach and a Column Generation-based epsilon approach were developed by considering short instances of clustered and random clients. The first experiments exhibit a competitive CPU time obtained by the latter approach. Also, it solves small and medium instances with an optimality gap smaller than 5%. Managerial insights on the impact of OD usage cost and CO2 are provided.

1 - Dispatching medical samples: a case study

Jean-Charles Billaut, Hélène Blasco, Marina Vinot

Amyotrophic Lateral Sclerosis (ALS) is a rare fatal motor neuron disease that causes degeneration of the upper and lower motor neurons. No diagnosis and prognosis biomarkers are identified to help patients' management and research in this field is highly active. Different ALS centers are in charge of patients' care in France with visits every 3 months for clinical and biological explorations. Many research projects are based on biological fluids samples exploration and involve different centers hospitals as ALS is considered as a rare disease. Consequently, the need to centralize samples in the specialized laboratories in charge of specific biological analyses is crucial. The question is how to organize the flow to optimize the use of these precious samples. Several biological fluids (blood, cerebrospinal fluid, etc.) are collected from each patient in each cohort in several tubes of varying quantities. Each product must reach the other centers, which express needs for each product. Three constraints complicate this (sort of graph flow) problem: (1) dividing a sample into several portions is a tedious aliquoting operation, (2) a shipment requires a freeze/thaw operation and (3) a patient sample cannot arrive in two different tubes at the same site. We minimize the maximum number of aliquoting operations and limit the number of freezing operations. We model this problem, show that it is NP-complete, propose an MILP model, a lower bound and a heuristic algorithm.

2 - A new class of premature, partial latin squares

Reinhardt Euler

A partial (i.e., partially filled) latin square PLS is called premature, if it is not completable to a full latin square (of the same order) but completable to such a latin square after deletion of any of its symbols. The complete knowledge of this kind of PLS would give an answer to the completable problem for latin squares in the following sense: a PLS can be completed if and only if it does not contain a premature PLS as a subsquare. One may also think of a hypergraph whose maximal independent sets are given by the full latin squares of a given order and whose hyperedges are to be described explicitly. We survey some known examples for a premature PLS and present a new class obtained from a combination of two well-known types.

3 - On the occurrence of optimally colored $\$K_t,t,\$$ in canonical 1-factorizations of complete graphs

Sebastian Urrutia, Dominique de Werra

Recoloring methods applied to optimally edge colored complete graphs of even size are fundamental components of local search procedures aiming to obtain 1-factorizations with specific properties. Then, there is an interest in finding in a 1-factorization, colored subgraphs that allow a local recoloring to obtain a new 1-factorization. The occurrence of bichromatic cycles, lanterns and optimally colored complete subgraphs in certain classes of 1-factorization has been previously studied. In this note we investigate the existence of optimally colored complete bipartite subgraphs in canonical 1-factorizations. We conclude that, whenever $\$n-1,\$$ is a prime number, no optimally colored complete bipartite subgraphs with more than 4 nodes occur in canonical 1-factorizations of complete graphs with $\$n,\$$ nodes. For other values of $\$n,\$$ we show that optimally colored complete bipartite subgraphs with more than 4 nodes do occur and we show how to construct some of them. For some small bipartite subgraphs the construction given is proven to be unique.

4 - On Minimum Euclidean Steiner Laman Graphs

Naoki Katoh, Hitomi Hayashi, Yuya Higashikawa, Takashi Horiyama, Risa Ishikawa, Yuki Kawakami, Yuki Kobayashi, Ayano Nishii, Junichi Teruyama, Yinfeng Xu, Azusa Yamamoto

An Euclidean Laman graph is a geometric graph on n vertices in the plane with exactly $2n - 3$ edges such that, for all $k > 1$, every k -vertex subgraph has at most $2k - 3$ edges. In this study, we introduce a variant of the well-known Euclidean Steiner tree problem, say the Euclidean Steiner Laman graph problem (ESL for short). Given a point set P in the plane, the goal is to find an Euclidean Laman graph of minimum total length such that any point in P is contained as one of its vertices. We also consider the problem of finding a plane (i.e., non-crossing) solution under the same setting, say the Euclidean Steiner plane Laman graph problem (ESPL for short).

First, we prove an optimal solution for ESL has no crossing, i.e., an optimal solution for ESPL is also optimal for ESL. Then, we design a polynomial time approximation algorithm that outputs a plane Laman graph and guarantees an approximation ratio at most asymptotically $1.5+$ with an arbitrarily positive ϵ .

1 - Robotic Assembly Line Balancing Problem Considering Uncertain Demand by Q-learning method

Yuchen Li

Coordinated decision making in manufacturing sector is crucial for business development. In this paper, a multi-objective robotic assembly line balancing problem is considered, which has the following features: 1) it involves a two-stage decision making process where the first stage is to design the robotic assembly line in terms of the task and robot assignment, and the second stage is to determine how much to produce for each product model; 2) the demand for each product is uncertain; 3) two objectives are considered including the number of workstations and carbon emissions. A reinforcement learning (Q-learning) method is devised to solve such problem. Computational studies are performed to validate the performance of the proposed algorithm.

2 - Robust optimization models for single-leg and network airline revenue management

Mustafa Pinar, Irem Bahtiyar, Ali Eren Demir, Itir Karaesmen

Effective capacity allocation methods play crucial roles in Revenue Management. Yet, current methods for determining optimal capacity controls under uncertainties, such as stochastic optimization, often assume a known distribution for unknown parameters. This assumption may degrade the model's performance when faced with unexpected data patterns. This paper explores a novel approach through robust optimization formulations for addressing stochastic resource allocation problems. We introduce heuristics based on these robust formulations to derive actionable results. Through extensive simulations focused on seat allocation problems within the revenue management domain, our proposed formulations demonstrate significantly improved worst-case performances. Notably, even under favorable scenarios, our solutions remain comparable to existing methods in the revenue management literature.

3 - Solution approaches for multi-source capacitated facility location problems with fairness objectives

Gianfranco Guastaroba, Carlo Filippi, Juan José Salazar González

Modern societies are developing an ever-increasing concern toward issues related to equity, often synonymously called fairness. In location problems, scholars soon realized the importance of incorporating equity in siting decision models. Often a decision-maker has to locate a set of facilities, which provide a service (or good) and are reached by customers at their own costs. In such situations, improving system efficiency requires minimizing the average cost paid by customers to reach a facility, while improving fairness requires minimizing the variability in the cost distribution. The latter is especially relevant in the public sector, where providing customers with a fair access is a crucial concern. We measure accessibility fairness by using the conditional beta-mean, which can be intuitively defined as the average distance traveled by beta% of the customers that travel the longest distances to reach the assigned facility. We show that incorporating such measure into a classic multi-source CFLP leads to a non-linear MIP. Borrowing some ideas from bilevel programming, we propose two linear reformulations of the latter MIP, and develop two solution methods that work along the general lines of a cutting-plane algorithm. Computational experiments show the effectiveness of the solution methods proposed. Further, a trade-off analysis between efficiency and fairness show that the proposed approaches may be used as managerial tools to balance these two objectives.

4 - A risk-averse latency location-routing problem with stochastic travel times

Francisco Saldanha-da-Gama, Alan Osorio-Mora, Paolo Toth

In this paper, a latency location routing problem with stochastic travel times is investigated. The problem is modeled as a two-stage stochastic program, by setting the location decisions at the first stage, and the routing decisions at the second one. A risk-averse decision-maker is assumed. An efficient and effective multi-start variable neighborhood search algorithm is proposed for tackling the problem. A sampling method is also presented for dealing with uncertainty captured by a continuous probability distribution. Several insights are provided based on the results of a series of computational tests performed to assess the methodological contributions provided by this work.

Counterfactual Analysis Across Diverse Domains

Stream: Mathematical Optimization for XAI

Invited session

Chair: [Jasone Ramírez-Ayerbe](#)

1 - Counterfactual Analysis for Explicability and Fault prevention of Complex Energy Systems

Martina Fischetti, Emilio Carrizosa, Juan Miguel Morales

Energy systems are often very complex systems, where different components interact in a not-trivial manner. In this context, identifying faults in the system and especially identifying their reason can be a complex engineering problem. Take for example an offshore wind farm. As offshore wind turbines can be very expensive to reach, faults are very expensive to handle. Therefore it is very important for energy companies to reliably identify real alarms. For this reason, many companies are nowadays using ML to identify failures. We would like to look a step further: we want to understand how the status of the turbine should be changed not to have a failure. We will use Counterfactual Analysis, once a classifier has been trained, to identify how records should be changed in their features to being classified in the "good"

class. Finding counterfactual explanations amounts to solving a mathematical optimization model, where we want to minimize the number of changes (or the total cost associated to changes) to an instance to maximize its probability of being classified as a good instance, subject to different constraints. We will present some preliminary results on the topic

2 - Contributions of surrogate models and counterfactual explanations to marketplace blackbox audits

Benoit Rottembourg, Jeanne Mouton, Jordan Thieyre

In a global context where competition authorities are investigating and sanctioning Amazon marketplace for practices of self-preferencing at the expense of their business users and consumers, we observe a trend of imposing remedies on dominant players in digital markets. Therefore, competition authorities and regulators need tools to audit the compliance of these dominant players in the e-commerce sector over the obligations and remedies they are imposing on dynamic, and personalized algorithms. Most of these algorithms embed Machine-Learning components, introducing opacity and potentially biases in the decision-making process.

The aim of our presentation is to explore the benefits of using black-box auditing techniques and counterfactual explanations to provide insights into the behavior of these online algorithms. We anchor our research in the literature of product preeminence from vertically integrated players, of choice ranking, and of the specific literature related to Amazon search ranking, automatic pricing and Buy Box's algorithms ([1];[2]). Through a longitudinal study of the ranking of several thousand products on Amazon, we will illustrate the potential of "surrogate" models and the decision-support elements they might provide.

3 - Counterfactual Analysis and Target Setting in Benchmarking

Dolores Romero Morales, Peter Bogetoft, Jasone Ramírez-Ayerbe

Data Envelopment Analysis (DEA) allows us to capture the complex relationship between multiple inputs and outputs in firms and organizations. Unfortunately, managers may find it hard to understand a DEA model and this may lead to mistrust in the analyses and to difficulties in deriving actionable information from the model. In this paper, we propose to use the ideas of target setting in DEA and of counterfactual analysis in Machine Learning to overcome these problems. We define DEA counterfactuals or targets as alternative combinations of inputs and outputs that are close to the original inputs and outputs of the firm and lead to desired improvements in its performance. We formulate the problem of finding counterfactuals as a bilevel optimization model. For a rich class of cost functions, reflecting the effort an inefficient firm will need to spend to change to its counterfactual, finding counterfactual explanations boils down to solving Mixed Integer Convex Quadratic Problems with linear constraints. We illustrate our approach using both a small numerical example and a real-world dataset on banking branches.

1 - Fair mixed effects support vector machine

João Vitor Pamplona, Jan Pablo Burgard

When using machine learning for automated prediction, it is important to account for fairness in the prediction. Fairness in machine learning aims to ensure that biases in the data and model inaccuracies do not lead to discriminatory decisions. E.g., predictions from fair machine learning models should not discriminate against sensitive variables such as sexual orientation and ethnicity.

A fundamental assumption in machine learning is the independence of observations. However, this assumption often doesn't hold true for data describing social phenomena, where data points are often clustered based. Hence, if the machine learning models do not account for the cluster correlations, the results may be biased. Especially high is the bias in cases where the cluster assignment is correlated to the variable of interest.

We present a fair mixed effects support vector machine algorithm that can handle both problems simultaneously. With a reproducible simulation study we demonstrate the impact of clustered data on the quality of fair machine learning predictions.

2 - A generalized voting game for categorical network choices

Yueh Lin, Stefano Nasini, Martine Labbé

This paper presents a game theoretical framework for data classification, based on the interplay of pairwise influences in multivariate choices. This consists of a voting game wherein individuals, connected through a weighted network, select features from a finite list. A voting rule captures the positive or negative influence of an individual's neighbours, categorized as attractive (friend-like relationships) or repulsive (enemy-like relationships). Payoffs are assigned based on the total number of matching choices from an individual's neighbours. We show that our approach constitutes a natural generalization of the K-nearest neighbours' method, establishing the proposed game as a theoretical framework for data classification. Computationally, we construct a mixed-integer linear programming formulation to approach the Nash equilibria of the game, facilitating their applicability to real-world data. Our results provide conditions for the existence of Nash equilibria and for the NP-completeness of its characterization. On the empirical side, we use the proposed approach to impute missing data and highlight its competitive advantage over the K-nearest neighbour's approach.

3 - Enhancing B2B customer retention: a streamlined profit-driven approach using fairness-inspired pre-processing techniques

Shimanto Rahman, Bram Janssens, Matthias Bogaert

In the realm of Customer Relationship Management, customer retention is pivotal for sustained growth. The positive correlation between customer satisfaction, retention, and profitability guides traditional Customer Churn Prediction models to rank high-value customers lower on average than their low-value counterparts. Ranking based on churn propensity without considering the profitability of retaining specific customers may lead to suboptimal decision-making. This is especially pronounced in Business-to-Business (B2B) industries. Various profit-driven metrics and algorithms address this, but their integration and extension demands considerable effort, hindering widespread adoption.

This paper proposes a streamlined approach, incorporating pre-processing techniques inspired by fairness literature, including Massaging, Reweighting, and Resampling. These techniques rectify the underrepresentation of high-value customers within the targeted group, improving churn campaign profitability. Preliminary results on two B2B datasets show these techniques outperforming baselines.

The research contributes by proposing techniques to amplify the often-underrepresented high-value customer fraction within the targeted group. Framing the challenge as one involving the sensitivity of high-value customers provides a simpler interface for improving churn campaign profit on par with existing profit-driven techniques.

4 - Analysing business intelligence adoption through natural language processing: a study of online customer testimonials

Masoud Fakhimi, Ashkan Lotfipoor, Alex Hagen-Zanker

Enterprises increasingly recognize the potential of business intelligence (BI) systems to enable data-informed decision-making. This study offers a novel, large-scale analysis of online customer testimonials to illuminate successful BI adoption patterns. Our research leverages natural language processing (NLP) techniques for systematic and thorough analysis of these rich, yet unstructured, data sources. Employing a qualitative approach, we used Python to scrape approximately 1000 testimonials from 'Customer Stories' sections of BI system websites (e.g., Power BI, Tableau, Knime). A large language model (LLM), Llama 2, was used to systematically extract and analyse key variables: motivations, implementation considerations, challenges, security concerns, monetization, collaboration, dynamic capabilities, and behaviour change. Our findings reveal common motivations for BI adoption, typical implementation pathways, and recurring challenges that organizations encounter. Additionally, the study uncovered how successful BI implementations monetize their data-driven insights and foster collaboration across teams. This customer-centric perspective will provide actionable guidance for businesses considering BI investments, enabling them to anticipate potential roadblocks and maximize the return on their BI initiatives.

Applications of combinatorial optimisation in industry and services I

Stream: Combinatorial Optimization

Invited session

Chair: José Fernando Oliveira

Chair: Adriana Cherri

1 - Multi-hospitals collaborative operating room scheduling with downstream capacity constraints

Yang Wang, Daiqiang Yin, Juanru Wang, Abraham Punnen, Zhipeng Lyu

We investigate a new multi-hospitals collaborative operating room scheduling problem with consideration of the downstream recovery beds to make integrated decisions from tactical and operational levels. For solving this challenging problem, we propose an effective multi-operator driven iterated tabu search (MOITS) algorithm to achieve a good search balance between intensification and diversification. The greedy initial solution construction procedure employs a priority scoring rule to sequence patients to obtain a high-quality initial schedule. The multi-operator driven tabu search procedure employs four move operators to manipulate surgeries in different OR time blocks, two move operators to change recovery hospitals of the scheduled surgeries, and one move operator to change specialties of the OR time blocks. New evaluation functions are designed for the recovery beds related move operators to allow capacity violations during the search. The elite set guided adaptive perturbation procedure uses historical information from a pool of best found solutions to adjust the OR time blocks assigned to each specialty. Experimental results indicate that our proposed MOITS algorithm is capable of finding much better solutions with an order-of-magnitude time reduction than Gurobi across problems of different sizes.

2 - Mathematical formulations for wood recycling optimization

Pauline Bessemans, Célia Paquay

The rising demand for materials such as wood undeniably contributes to the depletion of natural resources and global warming. Recycling

our wood waste intelligently could help to curb this phenomenon and have a significant ecological impact. This wood waste can be in the form of beams or pallets and could be considered as wood slats. They could be combined, assembled, and glued to create Cross-Laminated Timber (CLT) panels for the construction industry.

We aim to develop optimization techniques to recycle raw wood waste by providing the layout schemes to create CLT panels. The objective can be either to maximize the CLT panel production or to minimize the wood surplus when a given set of panels should be built.

We conducted a literature review to identify relatively similar problems in the operations research field. The skiving stock problem and the dual bin packing problem are the two closest problems to our. The second's name is quite misleading since our problem is technically not a dual version of the cutting stock/bin packing problem, but a problem on its own as shown in the literature.

In this work, we propose a clear description of our problem and different mathematical formulations with cuts for the variants. The results of various numerical experiments with field data from the wood industry are presented. As it is an NP-hard problem, we identify the limit size of the instances for which the problem can still be solved in a reasonable amount of time.

3 - Planning for a Transition to a Low Emissions profile for a large Commercial Vehicle Fleet

Brian Dangerfield

This presentation describes the formulation of a linear programming model and its use as a decision support tool to assess the phasing out of diesel vehicles and their replacement by low emission vans (LCV) and trucks (HGV). The company concerned offered one of the largest fleets of commercial rental vehicles in the UK and was keen to maintain its credentials with respect to decarbonisation. The main considerations for management were the planned lifetime of the various existing diesel vehicles, the likely capital budget for new vehicles, a company-set reduction in CO₂ emissions over the planning horizon, a reduction in the ratio of diesel to electric vehicles and all this in the context of a percentage annual growth rate for the total fleet size. The objective function was to minimise emissions over 5 years and one of the main outcomes was whether the company's planned profile for reduction in CO₂ emissions was feasible given the capital spending budget for new vehicles. The difference in purchasing costs of diesel and electric vehicles is quite considerable and, so to both adhere to the purchasing budget and achieve the planned emissions reductions, it would not be possible to adopt a cliff edge change in the vehicle purchasing profile. The continued acquisition of some diesel vehicles would be necessary. The model (developed using the Xpress platform) is described in detail along with the reaction of the company management to the results obtained.

4 - Exact and non-exact approaches for the multi-stage stochastic two-dimensional cutting stock problem with usable leftovers

Adriana Cherri, Douglas Nogueira do Nascimento, José Fernando Oliveira, Beatriz Brito Oliveira

The Two-Dimensional Cutting Stock Problem with Usable Leftovers (2D-CSPUL) consists of cutting large plates to produce smaller ordered items, minimizing waste and allowing the generation and subsequent use of leftovers. This work explores a multi-stage stochastic approach to the 2D-CSPUL, incorporating demand uncertainty over multiple periods and enabling more adaptive and resilient production strategies. By adopting a scenario-tree approach, the study represents uncertainties throughout the planning horizon, offering a closer reflection of real-world scenarios. Additionally, anticipatory production of items ahead of immediate demand is allowed. Costs associated with the storage of leftovers and the inventory of items are also considered. The objective is to minimize material waste and storage costs of items and leftovers across all stages. The main contribution of this paper is a new mathematical model proposed to represent this problem. Due to its complexity, heuristic procedures based on the relax-and-fix strategy were proposed to achieve practical solutions efficiently. Computational results prove the effectiveness of the three approaches. This research has been funded by the Fundação de Amparo a Pesquisa do Estado de

São Paulo - FAPESP, Brazil (Process number 2022/05803-3) and Conselho Nacional de Desenvolvimento Científico e Tecnológico - CNPq, Brazil (Process number 317460/2021-8).

Parallel Solvers

Stream: Software for Optimization

Invited session

Chair: Yuji Shinano

1 - Parallel General-Purpose Dynamic Programming Solvers for Combinatorial Optimization

Ryo Kuroiwa, Yuji Shinano, J. Christopher Beck

Domain-independent dynamic programming (DIDP) is a recently proposed model-based paradigm for combinatorial optimization based on dynamic programming (DP). In DIDP, similar to mathematical programming, a user formulates a combinatorial optimization problem as a declarative DP model and then solves the formulated model by calling a general-purpose solver. The currently developed DIDP solvers are based on heuristic search algorithms studied in the artificial intelligence community. In this work, we develop parallel DIDP solvers using parallel heuristic search algorithms. First, we empirically confirm that the multi-thread versions of our parallel DIDP solvers outperform commercial multi-thread mixed-integer programming and constraint programming solvers in multiple combinatorial optimization problems. Then, we develop distributed parallel DIDP solvers using the Message Passing Interface. Our experimental evaluation demonstrates the high scalability of the parallel DIDP solvers in a massively parallel distributed environment.

2 - A parallel Benders' decomposition algorithm for solving the integrated long-haul and local vehicle routing problem

Stephen Maher, Junko Hosoda, Yuji Shinano

The integrated long-haul and local vehicle routing problem with an adaptive transportation network is a very challenging optimisation problem. The adaptive nature of the transportation network means that the resulting optimisation problem is extremely large and difficult to solve using general purpose solvers. As such, only very small instances of this problem can be solved without the use of decomposition techniques. We propose a Benders' decomposition approach that identifies transportation network design in the master problem and then solves the integrated long-haul and local vehicle routing problem in the subproblem. The Benders' decomposition approach is used to solve a relaxation within a parallelisation framework that concurrently solves an iterative algorithm for finding high quality primal solutions. The results will show that applying Benders' decomposition increases the scale of problems that can be solved and improves the upper and lower bounds that can be achieved.

3 - Improving Lower Bounds for Large Scale QAPs

Koichi Fujii, Sunyoung Kim, Masakazu Kojima, Hans Mittelmann, Yuji Shinano

We report the progress of our project of solving large-scale Quadratic Assignment Problems (QAPs). We present a method that efficiently computes global lower bounds for QAPs by employing the Newton-bracketing method along with Lagrangian doubly nonnegative (DNN) relaxation. The integration of auxiliary information derived from the Newton-bracketing method, combined with the checkpoint mechanism of the parallelization framework Ubiquity Generator (UG), enables the determination of strong global lower bounds for large QAPs. This method has led to the improvement of lower bounds for several unsolved problems listed in QAPLIB, the standard benchmark for QAPs.

4 - Finding optimal solutions to previously unsolved combinatorial optimization problems by using more than 100,000 cores

Yuji Shinano

The Ubiquity Generator framework (UG) was originally designed to parallelize powerful state-of-the-art branch-and-bound based solvers (we call these "base solvers"). Two of the most intensively developed parallel solvers are FiberSCIP (for a shared memory computing environment) and ParaSCIP (for a distributed computing environment). Both of which use SCIP as the base solver. Since debugging on distributed environments is inefficient, FiberSCIP was developed, which has the same parallelization algorithms as ParaSCIP (since UG abstracts the parallelization library) but can run on a single PC. Due to the major debugging effort of UG and SCIP via FiberSCIP, ParaSCIP could solve more than 20 open instances from MIPLIB by using up to 80,000 cores and none of these results has been proven wrong so far. Since UG provides a systematic way to parallelize a state-of-the-art sequential or multi-threaded solver to run on a large-scale distributed memory environment, with version 1.0, UG is generalized to a software framework for high-level task parallelization. That is, with version 1.0, UG will not only parallelize the tree search of branch-and-bound-based solvers but allow the parallelization of other kinds of solvers. In this talk, we present the latest status for exactly solving previously unsolved instances of combinatorial optimization problems.

1 - Forecasting regional GDP using cointegration with business cycle indicators

Nariyasu Yamasawa

In Japan's local governments, the shortage of personnel has made it difficult to compile statistics. While regional Gross Domestic Product (GDP) is released promptly in countries like the United States and the United Kingdom, in Japan, there is a lag of about two years before annual figures are published. Several prefectures used to release preliminary figures for regional GDP on a quarterly basis, but their number has gradually decreased, and currently, only three prefectures do so. Many local governments are creating business cycle indices similar to the OECD's Composite Leading Indicator (CLI) to survey the current state of the economy. However, business cycle indices do not reveal the level of economic activity, nor do they easily allow for comparisons between different prefectures. In this study, a method to create regional GDP from business cycle indices was explored. It is assumed that there is a long-term stable relationship (cointegration) between the economic business cycle, which represent the cycle of the economy, and regional GDP, which represents the overall movement of the region. By constructing an Autoregressive Distributed Lag (ARDL) model and initially applying it to the country as a whole, a long-term relationship was confirmed. By applying this relationship to the Gross Regional Product (GRP) of each prefecture, a method to estimate regional GDP was devised.

2 - Modelling wind behaviour: using statistical distributions to represent wind speed and direction

Helena Alvelos, Francisco Marques, Ana Raquel Xambre, Agostinho Agra, Filipe Alvelos

Wildfires cause significant losses in both material value and human lives. Thus, preventing their occurrence or minimizing their impact when they do happen is paramount. Decision models have thus become increasingly popular in assisting the operational management of firefighting units. The management of wildfires can be divided into: (i) deployment, (ii) dispatch and (iii) positioning. Deployment decisions are made before the fire is detected, dispatch decisions are taken after the ignition is detected, and positioning decisions describe where the dispatched resources should suppress the fire. The study presented here is part of a project that combines two stages: the prepositioning (deployment) of resources, and the resource movement during the suppression (positioning). Naturally, the problem involves underlying uncertainty, two of its main sources being the ignition location and the wind properties. The study aims to obtain statistical information about the behaviour of wind speed and wind direction by modelling historical data of a case study region in Portugal. Several statistical distributions were tested using goodness of fit tests, in order to select the most appropriate probability distributions. The results were then used in the ambiguity set of a mixed integer programming distributionally robust optimization model.

Chair: Gerardo Toraldo

1 - An interior proximal gradient method for nonconvex optimization

Alberto De Marchi, Andreas Themelis

We consider structured minimization problems subject to smooth inequality constraints and present a flexible algorithm that combines interior point (IP) and proximal gradient schemes. While traditional IP methods cannot cope with nonsmooth objective functions and proximal algorithms cannot handle complicated constraints, their combined usage is shown to successfully compensate the respective shortcomings. We provide a theoretical characterization of the algorithm and its asymptotic properties, deriving convergence results for fully nonconvex problems, thus bridging the gap with previous works that successfully addressed the convex case. Our interior proximal gradient algorithm benefits from warm starting, generates strictly feasible iterates with decreasing objective value, and returns after finitely many iterations a primal-dual pair approximately satisfying suitable optimality conditions. As a byproduct of our analysis of proximal gradient iterations we demonstrate that a slight refinement of traditional backtracking techniques waives the need for upper bounding the stepsize sequence, as required in existing results for the nonconvex setting.

2 - Multilevel proximal methods for image restoration

Guillaume Lauga, Elisa Riccietti, Nelly Pustelnik

Solving high-dimensional optimisation problems is a difficult task, and numerous methods have been proposed to compensate for the high cost in computation time. The approach explored in this work exploits the structure of these optimisation problems, in order to reduce the computational cost of their solution.

Specifically, we focus on the multi-resolution structure at the heart of multi-level optimisation methods. These approaches take advantage of the definition of coarse approximations of the objective function to make its minimisation more efficient. In this talk, we present a proximal multilevel algorithm IML FISTA - Inexact Multilevel FISTA - suitable for the solution of optimisation problems where the non-smooth component of the objective function has no explicit formulation for the proximal operator.

The proposed method is then adapted to solve imaging problem in radio-astronomy. To reconstruct such images, a high number of observations in the Fourier space are combined. Such high number creates a computational bottleneck. We demonstrate that IML FISTA can provide considerable acceleration by using coarse approximation constructed in the observation space.

3 - A Scaled Gradient Projection method for the realization of the Balancing Principle in TGV-based image restoration

Germana Landi, Marco Viola, Fabiana Zama

In the last few years, Total Generalized Variation (TGV) regularization has proved to be a valuable tool to remove blur and noise from an image while avoiding the staircase effect and preserving the sharp edges. The TGV model depends on two regularization parameters whose values must be appropriately selected to obtain good-quality restored images. In this work, we use the Balancing Principle (BP) to formulate the TGV-based image restoration problem as a constrained minimization problem whose objective is an implicit function of the two regularization parameters depending on the image to be restored. The values of the regularization parameters, and the corresponding restored image, satisfying the optimality condition of the formulated problem guarantee that the data fidelity and regularization terms are balanced. A Scaled Gradient projection method is proposed specifically tailored to the BP-based optimization problem. The numerical results show that the proposed approach can effectively restore input images corrupted by several kinds of noise.

4 - A Variational Model for graph p-Laplacian eigenfunctions under p-orthogonality constraints

Giuseppe Antonio Recupero, Serena Morigi, Alessandro Lanza

The p-Laplacian is a non-linear generalization of the Laplace operator. In the graph context, its eigenfunctions are used for data clustering, spectral graph theory, dimensionality reduction and others problems, as non-linearity better captures the underlying geometry of the data. We formulate the p-Laplacian nonlinear eigenproblem as an optimization problem under p-orthogonality constraints. The problem of computing multiple eigenvectors of the graph p-Laplacian is then solved by iteratively minimizing the constrained generalized Rayleigh quotient. We analyze two different optimization algorithms to solve the variational problem. The first is a manifold gradient descent which solves a smooth unconstrained minimization over the p-orthogonality subspace. The second is an Alternate Direction Method of Multipliers which leverages the scaling invariance of Rayleigh quotient to solve a constrained minimization under a p-orthogonality constraint. We demonstrate the effectiveness and accuracy of the proposed algorithms and compare them in terms of efficiency.

Heterogeneity in optimal control problems

Stream: Optimal Control Theory and Applications

Invited session

Chair: Silvia Faggian

1 - Design of an ecological corridor surrounding restricted urban areas: An optimal control approach

Lino J. Alvarez-Vazquez, Néstor García-Chan, Aurea Martínez, Miguel E. Vazquez-Mendez

The use of optimization techniques for the optimal design of roads and railways has increased in recent years. The environmental impact of a layout is usually given in terms of the land use where it runs (avoiding some ecologically protected areas), without considering air pollution (in these or other sensitive areas) due to vehicular traffic on

the road. This work addresses this issue and proposes an automatic method for obtaining a specific corridor (optimal in terms of air pollution), where the economically optimized road must be designed in a later stage. Combining a 1D traffic simulation model with a 2D air pollution model and using classical techniques for optimal control of partial differential equations, the problem is formulated and solved in the framework of Mixed Integer Nonlinear Programming. The usefulness of this approach is shown in a real case study posed in a region that suffers from serious episodes of environmental pollution, the Guadalajara Metropolitan Area (Mexico).

2 - Self enforcing agreements, delayed information and taxes in a differential game modelling extraction of common renewable resources

Agnieszka Wiszniewska-Matyskiel, Rajani Singh

We analyse a differential Fish Wars game with n players and the infinite time horizon. We calculate the social optimum, a Nash equilibrium and partial cooperation equilibria. The Nash equilibrium always leads to depletion of fish, while the social optimum results in sustainability for a whole interval of parameters. Partial cooperation is in between, with the chance for sustainability growing with the number of cooperators, but only a coalition of size 2 is stable, which makes sustainability unlikely also in this regime. This is "the tragedy of the commons" in its most drastic form due to logarithmic payoff. We solve "the tragedy" by two frameworks to: either by an environmental agreement or by a tax-subsidy system. In the first framework, we analyse agreements in which each signatory reduces fishing to the social optimum level until they detect that another signatory has defected. We also assume it takes time to detect a defection. We are interested in the maximal detection time for which the agreement still remains self-enforcing. Counter-intuitively, it turns out that the more players, the higher this maximal detection time, so the more stable the agreement. Concerning the second framework, besides solving our specific "tragedy", we also propose a general algorithm for finding financial incentives enforcing the optimal profile in a large class of differential games and a large class of financial incentives or proving that such an incentive does not exist.

3 - Climate policy in a heterogeneous world

Giorgio Fabbri, Raouf Boucekkine, Fausto Gozzi, Cristiano Ricci, Ted Loch-Temzelides

We introduce a dynamic game framework that does not rely on linearity assumptions, while at the same time retaining tractability. As an illustration, we employ this framework to derive new insights on climate-related policy. We build a game-theoretic version of the dynamic integrated assessment model in Golosov et al. (2014). Our framework allows us to characterize emissions, consumption, and welfare across different equilibrium outcomes by computing the Nash and Stackelberg equilibria of a dynamic game capturing aspects of climate negotiations between the "global north" and "global south." We use these to draw various comparisons between such outcomes and the efficient frontier. We find that both the global north and the global south over-consume/pollute in the non-cooperative equilibria and the global south underinvests in abatement. Stackelberg leadership by the global north in climate negotiations reduces global emissions and increases welfare over the Nash outcome, although the emissions remain far from the optimum. Asymmetric vulnerability to climate change leads to a reversal in emissions, where the less vulnerable country emits more. We employ robust control to study how deep uncertainty affects outcomes.

4 - Symmetric equilibria in spatially distributed extraction games with non linear growth

Silvia Faggian, Giorgio Fabbri, Giuseppe Freni

This study examines the dynamics of the exploitation of a natural resource distributed among and flowing between several nodes connected via a weighted, directed network. The network represents the locations and interactions of the resource nodes. A regulator decides to designate some of the nodes as natural reserves where no exploitation is allowed. The remaining nodes are assigned (one-to-one) to players, who exploit the resource at the node. This study extends that in Fabbri

et al. (2024) to nonlinear dynamics of the capital stock evolution at the nodes, taking into account evolution equations of logistic or Solow type, establishing the existence of a Markovian equilibrium which is linear in the capital stock and confirming that, consistently with the case of a linear evolution, the equilibrium exploitation and resource stocks depend on the productivity of the resource sites, the structure of the connections between them, and the number and preferences of the agents. The best locations to host nature reserves are identified per the model's parameters and correspond to the most central (in the sense of eigenvector centrality) nodes of a suitably redefined network that considers the nodes' productivity.

1 - Enhancing the convergence speed of line search methods: Applications in Neural Network training

José Ángel Martín-Baos, Ricardo Garcia-Rodenas, Luis Rodriguez-Benitez, Maria Luz Lopez

The training of machine learning models, such as neural networks, relies on optimisation techniques that necessitate large volumes of data. The algorithms that have demonstrated satisfactory performance on this task frequently use linear searches on subsets of the data. This ensures that, despite the potential low quality of the search direction, the overall computational cost remains low, making this strategy globally efficient. In these methods, strategies employing a constant learning rate have proven to be particularly effective. This paper introduces a novel scheme designed to significantly expedite the convergence process of line search-based methods. Our approach incorporates additional high-quality linear searches derived from the convergence process of the methods, and by making use of an Armijo rule, it dynamically adjusts the step size through successive reductions or expansions based on the evaluated quality of the descent direction. This strategic adjustment enables more substantial progress in the search direction, potentially reducing the number of iterations needed to reach an optimal solution. We have applied our proposed solution to accelerate the performance of widely-used algorithms such as Gradient Descent (GD), Momentum GD, and Adaptive Moment Estimation (Adam). To illustrate the practical implications and effectiveness of our approach, we present a comprehensive case study focusing on the training of Deep Neural Networks and Kernel Logistic Regression.

2 - Sphere covering and approximating tensor norms

Zhening Li

The matrix spectral norm and nuclear norm appear in enormous applications. The generalization of these norms to higher-order tensors is becoming increasingly important, but unfortunately they are NP-hard to compute or even approximate. Although the two norms are dual to each other, the best-known approximation bound achieved by polynomial-time algorithms for the tensor nuclear norm is worse than that for the tensor spectral norm. We bridge this gap by proposing deterministic algorithms with the best bound for both tensor norms. The main idea is to construct a selection of unit vectors that can approximately represent the unit sphere, in other words, a collection of spherical caps to cover the sphere. For this purpose, we explicitly construct several collections of spherical caps for sphere covering with adjustable parameters for different levels of approximations and cardinalities. These readily available constructions are of independent interest, as they provide a powerful tool for various decision-making problems on spheres and related problems. Our results are generalized to the ℓ_p -sphere covering and approximating spectral and nuclear p -norms.

3 - First-order Trust-region Methods with Adaptive Sampling

Sara Shashaani

We are interested in optimizing noisy black-box problems that are non-convex in expectation. Such settings occur in a multitude of engineering and machine learning applications. For the noisy black-boxes that provide direct derivative observations, we devise new variants of trust-region methods that use adaptive sampling schemes and adjusted acceptance criteria to improve the iteration and sample complexity of these algorithms. The resulting methods will have clear implementable guidelines for speedy and robust finite-time performance.

1 - Scaled Cuts for Multistage Stochastic Mixed-Integer Programs

Ward Romeijnnders

We consider Benders' decomposition algorithms with affine optimality cuts for multistage stochastic mixed-integer programs. Exploiting extended spaces, we derive a hierarchy of convex polyhedral lower bounds for the expected cost to-go functions in the problem. These lower bounds, however, are not tight for mixed-integer state variables in general. That is why, we also introduce so-called scaled cuts. The advantage of these scaled cuts is that they allow for parametric non-linear feasibility cuts in later time stages, but that the optimality cuts for the expected cost to-go functions remain linear. We establish convergence by proving that the optimality cuts in the first stage recover the convex envelope of the first-stage expected cost to-go function.

2 - Uncertain standard quadratic optimization under distributional assumptions: a chance-constrained epigraphic approach

Daniel de Vicente, Immanuel Bomze

The standard quadratic optimization problem (StQP) consists of minimizing a quadratic form over the standard simplex. If the quadratic form is neither convex nor concave, the StQP is NP-hard. This problem has many relevant real-world applications ranging from portfolio optimization to machine learning. To accommodate uncertainty in the data matrix, we present a model with known distribution of the data matrix where both the StQP after realization, and the here-and-now problem are indefinite. Similarly to some robust formulations of uncertain StQPs, it turns out that a chance-constrained epigraphic StQP is in fact equivalent to a deterministic (possibly non-convex) StQP. We test the performance of a chance-constrained epigraphic StQP to the uncertain StQP by simulation.

3 - Gradient-Based Stochastic Optimization via Finite Differences: When To Randomize?

Michael Fu, Jiaqiao Hu

We consider optimization of noisy black-box functions via gradient search, where the gradient is estimated using finite differences. Applying a recently developed convergence rate analysis leads to a finite-time error bound for a class of problems with convex differentiable structures. The results provide insight as to when using randomized gradient approaches such as simultaneous perturbation stochastic approximation might be advantageous, based on problem dimension and noise levels.

4 - Guaranteed bounds for optimal stopping problems using kernel-based non-asymptotic uniform confidence bands

Martin Glanzer, Sebastian Maier, Georg Pflug

In this talk, a new approach is presented for obtaining guaranteed upper and lower bounds on the true optimal value of stopping problems by nonparametric regression. Unlike existing simulation-and-regression approaches, such as those based on least squares Monte Carlo and information relaxation, whose estimates depend on the sampled paths of the underlying stochastic process and are therefore stochastic in nature, our guaranteed bounds allow replacing the sampling error with a pre-specified confidence level. The key to our approach is the use of non-asymptotic uniform confidence bands based on a kernel ridge regression (KRR) estimator to over- and underestimate the conditional expected value from continuation. Since our high- and low-biased KRR estimators are guaranteed to over- and underestimate, respectively, the true but unknown conditional expectation at every step of the backward recursive procedure with a pre-specified confidence level, we obtain probabilistically guaranteed bounds on the problem's true optimal value. We derive closed-form formulas for both the fixed design and the random design case, which makes our approach readily applicable in both simulation and data-driven situations. We illustrate the applicability of the proposed bounding procedure by valuing a Bermudan-style put option.

1 - Bicriteria Nash Flows over Time

Tim Oosterwijk, Daniel Schmand, Marc Schröder

Traffic congestion imposes a huge economic loss. As such, there has been a huge effort to understand congestion using theoretical models. The dynamic model that gained most attention is the deterministic fluid queuing model. A common drawback of most models is that users only aim for minimizing their arrival time. However, users are not always that single-minded. We extend the state-of-the-art game theoretic traffic models with a multi-criteria objective function. We assume that users try to minimize costs subject to arriving at the sink before a given deadline. Here, costs could be thought of as an intrinsic preference regarding different route choices and queuing dynamics only play a role for the arrival time. We determine the existence and structure of Nash flows over time and fully characterize the price of anarchy for this model, which measures the ratio of the quality of the Nash flow and the optimal flow. We evaluate the quality both with respect to the throughput for a given deadline and the makespan for a given amount of flow. We prove the following results. (1) In series-parallel graphs, both prices of anarchy are unbounded. (2) In parallel path graphs the throughput-PoA is at most 2, or at most $e/(e-1)$ if all transit times are 0. Both bounds are tight. (3) In parallel path graphs the makespan-PoA is at most $e/(e-1)$, independent of transit times, and this is tight. All our upper bounds are also valid for dynamic equilibria in the deterministic fluid queuing model.

2 - Oligopoly Exploitation of Common-Pool Nonrenewable Resources: Price vs Quantity Competition

Luca Colombo, Paola Labrecciosa

It is a well-known result in static oligopoly theory that the Bertrand equilibrium (simultaneous price competition) is more efficient than the Cournot equilibrium (simultaneous quantity competition): consumers surplus and social welfare are higher in the former than in the latter. In this paper, we reconsider the validity of this efficiency result in a continuous-time duopoly game where production requires exploitation of a common-pool resource. The paper closest to ours is Colombo and Labrecciosa (JET 2015, CL henceforth). As in CL, we assume that the extracted resource is used in the production of horizontally differentiated products à la Singh and Vives (RAND 1984). Unlike CL, we assume that the resource is nonrenewable, that the marginal extraction cost is decreasing in the resource stock, and that the goods can be either substitutes or complements. A key assumption in our nonrenewable resource model is that there exists economic rather than physical exhaustion. The equilibrium concept we use is Markov Perfect Equilibrium. We are interested in equilibrium harvesting rates, consumers surplus, profits, and social welfare in the two different market structures. In contrast with static oligopoly literature, we show analytically that price competition does not necessarily lead to larger output, lower profits, larger consumers surplus and social welfare.

3 - A cooperative oligopoly with quantity goals

Maria de los Angeles Caraballo, Asunción Zapata, Luisa Monroy, Amparo Mármol

This paper considers an extended setting of a Cournot oligopoly in which firms face a cost when deviating from a fixed quantity that is exogenously given. To analyze these situations, we assume that firms show a cooperative behavior. The literature usually describes cooperation as the act of cooperation between competing firms by forming a strategic alliance designed to achieve mutual benefits and competitive advantages. Based on this concept, we consider that a firm has a cooperative behavior when it cares both about its own utility (competition) and also, at least, about the utility of one of the others (cooperation). Moreover, depending on the attitude that a cooperative firm exhibits with respect to the utilities of the others, different types of firm can be distinguished. Within this framework, the aim of this paper is to analyze the effects of the degree of cooperation on the quantity offered by the firms at equilibrium. Interestingly, we show that in some situations, the firms with a higher degree of cooperation drive the less cooperative firms out of the market. Furthermore, we obtain the path of equilibrium quantities for a set of values for the degree of cooperation.

4 - Learning and Forgetting in Oligopoly

Paola Labrecciosa, Luca Colombo

In this paper, we are interested in assessing how changing the market structure interacts with learning spillovers and organizational forgetting to affect incentives to innovate via learning. In particular, we are interested in studying the relationship between market competition and learning-by-doing, a type of innovation, aiming to contribute to the classical debate over the relationship between market structure and innovation. We provide conditions under which a symmetric Closed-Loop Nash Equilibrium exists. Then we conduct a comparative steady state analysis with respect to the parameters of the model. The main conclusion of our analysis is that conditions on the diffusion rate of knowledge and the rate of organizational forgetting exist under which an increase in market competition is not necessarily welfare-enhancing.

1 - A survey on polyhedral convex set optimization

Andreas Löhne

Set optimization is a generalization of multiobjective optimization where a value of the objective mapping is not a single vector but a set of vectors. Polyhedral convex set optimization is the simplest class of set optimization problems comparable to linear programming in the field of scalar optimization. We survey some recent developments including solution concepts, solution methods and applications.

2 - Dimension reduction in multiobjective optimization

Ina Lammel, Volker Maag

Many real-world optimization problems depend on several criteria. The computational effort of approximating the nondominated set of these multiobjective optimization problems increases quickly with the number of objectives. For a large number of objectives, computing a good approximation of the nondominated set may exceed the available computation budget.

To compute approximations of high-dimensional nondominated sets, we incorporate dimension reduction techniques into the approximation process. We analyze the problem to identify strongly-correlated directions of the nondominated set and reduce the objective space dimension accordingly. After computing an approximation in the lower-dimensional space, we project the approximation back to the original full-dimensional space. We relate the approximation of the nondominated set constructed by this algorithm to the approximation of the full-dimensional set and develop criteria under which the approximation in lower-dimensional space still yields a good approximation when projected back to the full-dimensional space.

Finally, we demonstrate the usefulness of the method on examples from different fields of application.

3 - Weight Space Decomposition for Multiobjective Linear Programming in the Context of Equitable Optimization

Firdevs Ulus, Ozlem Karsu

We consider equitable linear optimization problems (ELOP), which are multiobjective optimization problems, with each objective representing the benefit that one entity receives. In such problems, the concept of dominance is replaced by equitable dominance. The aim is to find the set of equitably nondominated points, which can be done by solving ordered weighted averaging (OWA) scalarization. Each solution corresponds to a different set of weights that make the solution optimal, hence a different degree of inequity aversion. We discuss a novel use of the parametric simplex algorithm to address ELOP. The algorithm not only provides the set of equitably nondominated solutions but also yields the corresponding weight space decomposition. We also propose an alternative method based on geometric duality to compute the weight space decomposition given the set of nondominated solutions.

4 - DMulti-MADS, a Multiobjective Algorithm for Constrained Derivative-Free Optimization

Ludovic Salomon

The last decade has seen the development of new convergence-based derivative-free algorithms. Among them, DMulti-MADS is a direct search algorithm, which extends the single-objective algorithm MADS to multiobjective optimization. In this talk, we present recent improvements to this method, from the consideration of general inequality constraints and mixed-integer variables to the development of new search heuristics. We illustrate the performance of these new features in numerical experiments and engineering applications.

Special Classes of Convex Conic Optimization problems

Stream: Conic Optimization: Theory, Algorithms, and Applications

Invited session

Chair: Tatiana Tchemisova

Chair: Olga Kostyukova

1 - Duality gap and examples in infinite-dimensional conic linear programming problems

Constantin Zalinescu

It is well known that the use of Rockafellar's perturbation method is very efficient for getting duality results in convex analysis. The use of this method in linear programming is less spread. It is our aim to show that, using Rockafellar's perturbation method, one can obtain duality results in infinite-dimensional conic linear programming under very general conditions. Moreover, we analyze a sample of Kretschmer's gap example used in N.E. Gretskey, J.M. Ostroy and W.R. Zame's paper Subdifferentiability and the duality gap, Positivity 6 (2002), 261-274.

2 - Conic optimization problems over semidefinite plus nonnegative cone

Tatiana Tchemisova, Olga Kostyukova

The paper is dedicated to optimization of linear functions over the cone of doubly non-negative matrices and its dual, the sum of semidefinite plus nonnegative cones. Several equivalent conditions of strict complementarity and nongeneracy are given. The findings are illustrated with examples.

3 - Refined TSSOS

Daria Shaydurova, Volker Kaibel, Sebastian Sager

The moment-sum of squares hierarchy by Lasserre has become an established technique for solving polynomial optimization problems. It provides a monotonically increasing series of tight bounds, but has well-known scalability limitations. For structured optimization problems, the term-sparsity SOS (TSSOS) approach scales much better due to block-diagonal matrices, obtained by completing the connected components of adjacency graphs. This block structure can be exploited by semidefinite programming solvers, for which the overall runtime then depends heavily on the size of the largest block. However, already the first step of the TSSOS hierarchy may result in large diagonal blocks. We suggest a new approach that refines TSSOS iterations using combinatorial optimization and results in block-diagonal matrices with reduced maximum block sizes. Numerical results on a benchmark library show the large potential for computational speedup for unconstrained and constrained polynomial optimization problems, while obtaining almost identical bounds in comparison to established methods.

Stochastic Models in Service Operations I

Stream: Stochastic Modelling

Invited session

Chair: Benjamin Legros

1 - Quality-Speed Trade-Offs in Dynamic Service Systems: How to Anticipate Future Demand Changes

Raik Stolletz, Jannik Vogel, Tim Weber

Quality-speed trade-offs occur in many service systems in which employees have discretion over their service times. An increase in service time often results in an increase in the quality of a service but also increases congestion. We investigate this trade-off in a dynamic setting with time-dependent and stochastic demand. To the best of our knowledge, this work is the first analysis of the quality-speed trade-off with exogenous changes in the demand. It shows how service providers can anticipate future expected demand changes with optimized service rates.

We investigate a piecewise-stationary approach whereby periods are not interrelated. Based in this, a closed-form stationary smoothing heuristic accounts for future demand changes. A performance evaluation based on a stationary backlog-carryover (SBC) approach considers the interrelations of performance measures between periods directly, and hence, allows to determine service rates simultaneously over all periods of the planning horizon.

We show that forecasted demand changes are anticipated by service rates several periods in advance. Substantial benefits are achieved by incorporating forecasted demand changes in the decision making of time-dependent service systems affected by the quality-speed trade-off.

2 - Modelling and Optimization for Service System with Ticket Queues

Chesoong Kim

Classical queuing models assume that each incoming user is accepted into the system if there is at least one free space in the queue and is served in a certain order. However, frequently in real systems, users may be impatient and leave the system after some waiting time if their service has not begun. Another kind of practically important and interesting queues is so-called ticket queues. In such queues, each arriving user receives a numbered ticket and observes the number of the user being served, which is broadcast on a display panel. In a ticket queue, no physical queue is formed. Thus, based on information about the difference between his own number and the displayed number, the user decides whether to balk or wait for service. In contrast to the usual queues with balking users, the balking user in ticket queues leaves the system physically, but his number remains in the queue. We consider a ticket queueing system with a finite buffer of capacity. Arriving users obtain a ticket for service but may balk the system with the probability depending on the queue of tickets ahead of customers. Tickets issued to users remain in the ticket buffer whether they participate or not. The server is unaware about the presence of users in the system and spends some time for their service even the respective user already left the system. In this paper, good reviews of relevant research are presented and the stationary distribution of the considered system is analyzed.

3 - Improving Congestion in an Efficient & Robust manner using time slotting at Airport Security

Joris Slootweg, Rob van der Mei

We show that the efficiency of the security process at airports can be significantly improved by adoption of a system where passengers are able to book a time slot. This time slot allows passengers to get priority access at the given time for security. We show that a simple load balancing heuristic already guarantees that participants have minimal waiting time while at the same time reducing the average waiting time of all passengers. Our proposed method is able to reduce the waiting time even further. Furthermore, our approach specifically takes into consideration the uncertainty in the arrival pattern and security capacity at the moment the time slots need to be allocated. Therefore, it can guarantee minimal waiting time in all scenarios for participating passengers. Furthermore, this approach leads to significantly lower wait time for non-participants than the baseline heuristic or having no virtual queuing at all in almost all scenarios. Finally our numerical experiments show that our approach is able to reduce the sensitivity to the uncertainty in the arrival behavior of passengers and the security capacity.

4 - Why rational queueing of delay risk-sensitive users undermines the benefits of added resources

Benjamin Legros, Johan van Leeuwen, Jan C. Fransoo

While policymakers regularly add capacity to reduce congestion in public services like roads and hospitals, empirical studies show that adding resources does not always reduce congestion and delays. To clarify this phenomenon, we propose an explanatory model of rational delay-risk sensitive users who are less inclined to access services when delays are more variable. Using a rational queueing approach, we show that there are largely two opposite effects of increased resource capacity. The public interest benefits through improved throughput and social welfare, while individual users can experience degraded service in terms of expected delays. We offer as an explanation that adding resource capacity reduces delay variability, so that delay-risk sensitive users will more readily join. In addition, we show that resource capacity not only influences the volume of demand but also its nature: increased service capacity attracts users who are less sensitive to expected delays and more sensitive to delay variability, which implies that large-capacity systems predominantly attract users who prefer reliability over efficiency.

Queueing Models with Strategic Customers

Stream: Advances in Stochastic Modelling and Learning Methods

Invited session

Chair: Odysseas Kanavetas

1 - Reneging behavior of customers in a queueing system subject to breakdowns and repairs

Dimitrios Logothetis, Odysseas Kanavetas

We consider a Markovian queueing system with a single server which is subject to breakdowns. When a breakdown occurs, the server continues its operation but at a reduced service speed. The repair process initiates only when the system is empty and during that time, customers continue to accumulate without receiving service. Customers are strategic, and while observing the state of the system, they may choose to renege at any point. To study the impact of reneging behavior, we also consider a similar model where reneging is prohibited, and customers only decide whether to join the system or to balk. In these scenarios, we derive the equilibrium strategy of the customers and we compute the steady state distribution under equilibrium. In particular, we find that in equilibrium, the customers follow a triple threshold strategy which we characterize. To analyze the effect of the customer reneging behavior, we conduct a theoretical comparison of these systems and perform several numerical experiments. We identify cases where reneging is beneficial in terms of social welfare, as well as cases where prohibiting reneging ensures greater welfare.

2 - Learning and pricing in queues with unobserved balking

Shreehari Bodas, Michel Mandjes, Liron Ravner

Impatience of customers plays a crucial role in modelling service systems. In many situations, any arriving customer is informed about the current congestion level. In this way they can obtain a sense of their prospective waiting time, based on which they can decide whether or not to join. If this waiting time exceeds their patience threshold, they balk; otherwise they join. In this talk we discuss queues with impatient customers, by in particular considering a relevant related decision problem: how to set a fixed admission price so as to maximize revenues? We discuss approaches based on applying existing techniques such as Stochastic Gradient Descent via Infinitesimal Perturbation Analysis and Stochastic Approximation methods such as the Kiefer-Wolfowitz algorithm.

3 - Strategic reneging in service systems with working breakdowns

Odysseas Kanavetas, Dimitrios Logothetis, Athanasia Manou

In this study, we analyze the reneging behavior of customers in a Markovian M/M/1 queue with an alternating service process, representing a normal operation mode and a working repair mode with reduced service speed. The customers are strategic and, as they continuously observe the system's state, they decide whether to stay or to renege. For this model, we derive equilibrium customer reneging strategies and the corresponding performance measures of the system, considering both the baseline model with discrete units of customers and its fluid counterpart. To capture the effect of reneging, we compare their performance with similar systems, operating under a no-reneging policy. Both theoretical findings, as well as numerical experiments, reveal that allowing reneging significantly affects system performance. Finally, to assess the quality of the fluid approximation we conduct a numerical comparison between the fluid and the baseline version of the model.

Optimization on Geodesic Metric Spaces II: Nonsmooth case

Stream: Optimization on Geodesic Metric Spaces: Smooth and Nonsmooth

Invited session

Chair: Alexandru Kristaly

1 - Convergence and stability of optimal transport on irreversible metric spaces

Wei Zhao

The talk is devoted to the optimal transport on irreversible metric spaces. While the compact setting is mostly similar to the reversible case developed by J. Lott, K.-T. Sturm and C. Villani, the noncompact case provides various surprising phenomena. Since the reversibility of noncompact irreversible spaces might be infinite, it is motivated to introduce a suitable nondecreasing function that bounds the reversibility of larger and larger balls. By this approach, we are able to prove satisfactory convergence/stability results in a suitable - reversibility depending - Gromov-Hausdorff topology. A wide class of irreversible spaces is provided by Finsler manifolds, which serve to construct various model examples by pointing out genuine differences between the reversible and irreversible settings. It is a joint work with Alexandru Kristaly.

2 - Hardy inequalities via Riccati pairs

Sándor Kajántó

We present a simple approach for proving Hardy inequalities on Riemannian manifolds, with sectional curvature bounded from above. By using simple convexity arguments and divergence/comparison theorems, we show that the validity of these inequalities reduces to the solvability of corresponding Riccati-type differential inequalities. Since the proofs omit symmetrizations, the method allows for broad applicability: inequalities formulated on model space forms naturally extend to manifolds with smaller sectional curvature.

3 - Sharp functional inequalities on metric measures spaces via optimal transport theory

Alexandru Kristaly

In this talk we present some sharp functional (Sobolev, log-Sobolev) inequalities on metric measure spaces that are curved in the sense of Lott-Sturm-Villani, by using optimal transport theory. As an application, we provide a sharp weighted hypercontractivity estimate for the Hopf-Lax semigroup related to the Hamilton-Jacobi equation.

Quantum Computing for Continuous Optimization

Stream: Quantum Computing Optimization
Invited session

Chair: Sander Gribling

1 - Solving quadratic binary optimization problems using quantum SDP methods: Non-asymptotic run-time analysis

Fabian Henze, Viet Tran, Birte Ostermann, Richard Kueng, Timo de Wolf, David Gross

In principle, quantum computers can solve semi-definite programs using resources that scale extremely well in the matrix dimension, though very unfavorably in the precision. In 2019, Brandao, Franca, and Kueng proposed to use quantum SDP solvers in order to speed up the Goeman-Williams-type relaxations of combinatorial optimization problems. One motivation for their ansatz was that the final rounding step that maps SDP solutions to binary variables should be comparatively insensitive to limits in the precision. They did indeed succeed to identify an algorithm that achieves an asymptotic quadratic speedup over state-of-the-art classical methods. Here, we present an analysis of the non-asymptotic resource requirements of this ansatz. The work consists of two parts. First, we optimize the original algorithm with a view on performance for finite problem instances. In particular, we formulate a version with adaptive step-sizes, an improved detection criterion for infeasible instances, and a more efficient rounding procedure. In a second step, we benchmark both the classical and the quantum version of the algorithm against synthetic and real-world data. Unfortunately, we find that even the optimized quantum algorithm will not beat more standard classical approaches for input sizes that can be realistically solved at all.

2 - Quantum speedups for linear programming via interior point methods

Sander Gribling

We describe a quantum algorithm based on an interior point method for solving a linear program with n inequality constraints on d variables. The algorithm explicitly returns a feasible solution that is ϵ -close to optimal, and runs in time $O(\sqrt{dn} \text{poly}(d, \log(n), \log(1/\epsilon)))$ which is sublinear for tall linear programs (i.e., $n \gg d$). Our algorithm speeds up the Newton step in the state-of-the-art interior point method of Lee and Sidford [FOCS '14]. This requires us to efficiently approximate the Hessian and gradient of the barrier function, and these are our main contributions.

To approximate the Hessian, we describe a quantum algorithm for the spectral approximation of AT^tA for a tall n -by- d matrix A . The algorithm uses leverage score sampling in combination with Grover search, and returns a delta-approximation by making $O(\sqrt{nd}/\delta)$ row queries to A . This generalizes an earlier quantum speedup for graph sparsification by Apers and de Wolf [FOCS '20]. To approximate the gradient, we use a recent quantum algorithm for multivariate mean estimation by Cornelissen, Hamoudi and Jerbi [STOC '22]. While a naive implementation introduces a dependence on the condition number of the Hessian, we avoid this by pre-conditioning our random variable using our quantum algorithm for spectral approximation.

Simulation in innovation

Stream: Agent-based Models in Management, Economic

and Organisation Sciences

Invited session

Chair: Theresa Elbracht

1 - Decision-making Modeling and Simulation of Digital Platform Innovation Team based on Member Interaction

Yanqiu Song, Junlin Chen, Tanxiaosi Luo

Our research proceeds in three ways. Firstly, we identify patterns of member interaction and key influencing factors via brings together developments in the literature over the past several years. Second, key influencing factors are included in the team decision model to build interactive team decision rules containing the individual member decision rules and the overall team decision rules. Finally, the simulation model of team decision is built on the Anylogic platform to verify the dynamic evolution of innovative team interactive decision in the digital platform system. Our principal contributions can be highlighted as follows: (1) Literature research has found that the factors that affect the interactive decision-making of innovation teams include the individual cognitive level of members, risk preferences, and member satisfaction. (2) If there are significant differences in risk preferences among team members, they may find it difficult to reach consensus quickly during decision-making and exhibit conflicting behaviors in repeated decision-making, resulting in low innovation value in the decision-making outcomes. (3) A team with a high level of cognitive ability is more likely to form higher innovative value in decision-making. (4) In repeated interactive team decisions, satisfaction can affect members' willingness to communicate and change their choices, thereby affecting the team's decision-making outcomes.

2 - Innovation diffusion in the presence of opposing information sources: An agent-based simulation approach

Frederik Tolkmitt, Christian Stummer

The market introduction of radically new products and their respective innovation diffusion can considerably be affected by consumers' increased uncertainty due to diverging information received from opposing sources. Such information can originate, for example, from strong general attitudes being prevalent in certain consumer groups (e.g., regarding the pros and cons of integrating AI capabilities in products) or it may even be spread by a competitor employing a negative-word-of-mouth campaign (e.g., when questioning the eco friendliness of electric vehicles). In such a setting, consumers receive ambiguous signals, which should increase their uncertainty and potentially delay product adoption. However, commonly used belief updating models (such as Bayesian learning), in a counterfactual manner, assume a decrease of uncertainty whenever new information is received even if this information substantially deviates from previous information. In our research, we demonstrate this effect by means of a computational simulation experiment based on a straightforward agent-based model of innovation diffusion and we propose a novel approach that more realistically captures consumer uncertainty with respect to insufficient or ambiguous information.

3 - The heterogeneity effect in modeling innovation diffusion: Findings from an agent-based simulation experiment

Theresa Elbracht, Christian Stummer

Analytical models of innovation diffusion need to reduce real-world complexity in order to be numerically tractable. The seminal Bass model, for example, assumes (i) that consumers are fully connected to each other and thus are correctly informed about the share of adopters in the population at each point in time and (ii) that consumers are identical in their innovativeness and their propensity to conform with others. Both assumptions are counterfactual with respect to real consumers, who can only oversee the behavior of a limited set of peers and have individual traits (e.g., some are innovators in adopting new products and do not care much about the share of adopters among their immediate peers, while others are laggards). In our research, we investigate whether accounting for consumer heterogeneity makes a difference with respect to a better fitting of computed sales to real-world sales (with data taken from Bass's work).

As a means of introducing consumer heterogeneity in an innovation diffusion model, we exploit the strengths of agent-based modeling,

which allows us to connect consumers through a realistic social network and assign them individual attitudes (drawn from a normal distribution around the population's mean values provided by Bass). Our talk details the setup of four simulation experiments in which we vary consumer heterogeneity in the two above-mentioned dimensions, and discuss our findings.

Robustness analysis in MCDA 2

Stream: Multiple Criteria Decision Analysis
Invited session

Chair: Nikos Tsotsolas

1 - Resolving Ambiguous Preference Information in Group Decision-Making: A Novel Optimization Model for Consensus-Reaching

Jutta Geldermann, He Huang, Erik Pohl, Cathy Macharis, Sebastian Schär

Within many multi-attribute decision-making (MADM) methods, inter-criterial preferences of the decision-makers (DMs) are expressed via criteria weights. Due to its convenience and simplicity, the revised method of Simos is widely applied to elicit criteria weights interactively with the DMs. Especially in group decision-making situations it provides procedural ease and offers a means to engage the dialogue with and in between DMs. In Simos' method, each DM orders a set of criteria cards according to their relative importance to derive criteria weights. However, this can lead to ambiguous preference mappings and thus ambiguous criteria weight vectors. Therefore, the robust extension of Simos' method determines all possible weight vectors from an ordered set of criteria cards via linear programming, where the set of feasible solutions forms a hyper-polyhedron. Although the concerns about robustness are expressed in the scientific literature on Simos' method, there is currently no methodological approach to process this information for consensus-reaching in decision problems with multiple DMs. We present an optimization model that determines a consensual alternative by utilizing the ambiguity of Simos' method. The model is based on the preference ranking organization method for enrichment evaluation (PROMETHEE) and demonstrated at hand of a case study for the assessment of seawater desalination plant concepts in Jordan.

2 - A Comprehensive Framework for Multi-Criteria Sorting Model Selection Based on Experimental Analysis of Model Expressiveness and Robustness of Recommendation

Michał Wójcik, Miłosz Kadzinski, Moha Ghaderi

We present research results on the expressiveness of models and the robustness of recommendations for various approaches to solving the value-driven threshold-based multiple criteria sorting problem. The basic model we consider is UTADIS, which assumes the evaluation of alternatives based on monotonic, preferentially independent criteria. We also present several extensions to the model. Some of them relax monotonicity constraints, and others introduce interactions between criteria. The considerations focus on the preference disaggregation paradigm, reproducing the Decision Maker's preferences, expressed as assignment examples. We present the results of the performed experimental analysis for six different approaches, focusing on the aspect of expressiveness, which is the ability to reproduce indirectly expressed preferences, and robustness, which determines the stability of the recommended assignments, tested based on all models consistent with the provided recommendations, using Robust Ordinal Regression and Stochastic Multicriteria Acceptability Analysis. The analysis results were presented and discussed based on seven quality measures, divided into the considered problem dimensions, such as the number of classes, criteria, characteristic points in marginal functions,

and the richness of knowledge provided by the DM. The analysis captured the trade-off between the considered aspects, indicating that more flexible approaches with richer representation provide more expressive

3 - Modeling of Stochastic UTADis and its application in a DSS addressing agrofood marketing decisions

Nikos Tsotsolas

A DSS has been developed to support B2B marketing strategy regarding agrofood products based on previous buying decisions. The DSS collects data directly from a blockchain B2B platform, which supports the whole procurement process from farm to fork. These marketing decisions refer to the determination of values of products' characteristics, such as price, quality, certifications, logistics, for a better market placement of a specific product. Following the aggregation-disaggregation approach the preference models of different buyers are elicited based on their buying behavior of competitive products. The present research discusses the modeling and application in the DSS of a specific form of UTADis method, which encompasses the notions of Stochastic UTADis in order to deal with several evaluations of products characteristics in various B2B negotiations and transactions that lead to different buying decisions. The modified method is called Stochastic UTADis and its application allow the users of the DSS to evaluate different marketing mix scenarios resulting to the allocation of a product into three predefined buying decision categories.

4 - Strategic Categorization of Swiss Energy Policies: A Robust Hybrid MCDA Approach for Socio-Political Assessment

He Huang, Eleftherios Siskos, Peter Burgherr

In pursuit of climate neutrality and increased energy security, Switzerland's transition to renewable energy needs to be steered by key energy policies. However, socio-political barriers, such as social acceptance, rather than technical constraints, mostly hinder the successful implementation of these policies. Such socio-political aspects need to be better understood, examined and accounted for during energy policy analysis and consultation. To address this need, we propose a hybrid multi-criteria decision analysis (MCDA) framework that integrates the fuzzy best-worst method (BWM) with PROMETHEE II and incorporates a comprehensive assessment of energy policy risks and benefits by an expert. This approach not only elicits the socio-political dimensions of policy performance, but also employs a strategic sorting technique for targeted action plans. The methodological framework is coupled with a robustness analysis that validates the reliability of the results under different future scenarios, ensuring the resilience of policy recommendations under uncertainty. The findings prove the efficacy of the framework to address uncertainties and include the social element in robust policy assessment and strategic planning.

Multiple-Criteria Decision Support

Stream: Decision Support Systems

Invited session

Chair: Pavlos Delias

1 - Development of strategic map (BSC) with fuzzy logic and multi-criteria optimization

Armando Meza, Juan Perez, Héctor López-Ospina, Luis Quezada

The most relevant task for the implementation of the Balanced Scorecard is the mapping of strategies since it provides a structure to demonstrate how strategies link the intangible properties of an organization with the value creation process, in turn; it shows how the objectives of the different perspectives are related to achieving the vision. This research contributes to models and cutting-edge methodologies in the

context of the systematic development of strategic maps of organizations through the creation of a framework to help in decision-making. Our objective is the design of a methodology that supports the construction of strategic maps in organizations through the implementation of multi-criteria decision making and optimization methods that allow for establishing and reducing causal relationships between the strategic objectives of the 4 perspectives of the BSC (Learning and Growth, Internal Processes, Customers and Financial) and the selection of the most representative for the fulfillment of the strategy. The MCDM used to meet the objective was DEMATEL determining the causal relationships and the effects of the variables of the strategic map with the information obtained from a group of experts. The linear programming optimization model that was applied is based on the reduction of arcs within the strategic map, eliminating the objectives that obtained the lowest rating in the expert consultation and the maximization of the selected financial objectives.

2 - Integrating uncertainties in a multi-criteria decision analysis with the ENTSCHIEDUNGSNAVI

Mendy Tönsfeuerborn, Sven Peters, Rüdiger von Nitzsch

The ENTSCHIEDUNGSNAVI is an open-source decision support system based on multi-attribute utility theory, which has implemented various methods for dealing with uncertainties. To model decisions with uncertainties, decision-makers can use two categories: Forecast and Parameter Uncertainty. Forecast uncertainty is modeled with (combined) influence factors using discrete, user-defined probability distributions or predefined 'worst-median-best' distributions. Parameter Uncertainty allows imprecision for utilities, objective weights, and probability distributions. To analyze these uncertainties, the ENTSCHIEDUNGSNAVI offers several methods and tools, like a robustness check, based on (Monte Carlo) simulations and a sensitivity analysis. The objective weight analysis provides insights into the effects of different objective weight combinations. Indicator impacts, tornado diagrams, and risk profiles visualize the impact of uncertainties in a decision under risk. The latter enables a check for stochastic and simulation dominance. This article presents a complete range of methods for dealing with uncertainties in the ENTSCHIEDUNGSNAVI using a hypothetical case study.

3 - SAPEVO-H' a Hybrid and Hierarchical Decision Support System for Multi-Criteria Analysis in Complex Environments

Miguel Ângelo Lellis Moreira, Teresa Pereira, Marcos Santos, Carlos Francisco Simoes Gomes

In the realm of decision-making within highly complex environments, evolving numerous variables, circumstances, scenarios, and multiple decision-makers with different perspectives and knowledge concerning a problematic situation, the study proposes extensive modelling for the SAPEVO multi-criteria family of methods. The new modelling, SAPEVO-H', exposes a novel hybrid and hierarchical approach, promoting multi-criteria analysis facing the evaluation of a hierarchical structure of variables assessed by distinct decision-makers, segmented according to their specific areas of responsibility. The model embodies an axiomatic enhancement, enabling a more versatile analysis that accommodates quantitative and qualitative data. A notable feature of SAPEVO-H' is its capacity for group evaluation, organizing stakeholders into levels and assigning variables based on their expertise and prior knowledge without attributing disproportionate influence to any single decision-maker. To support practical application, we present an online computational platform. This technological framework fosters integration among diverse decision-making groups through an asynchronous evaluation environment, enhancing transparency in the decision-making process. It reveals individual and collective preferences alongside the traceability of utility construction, elucidating the intricate relationships among variables, established preferences, and the connections between stakeholder perceptions.

4 - Choice and the Machine: overcoming the challenge in the selection of multiple criteria decision analysis method through the use of large language model.

Aritad Choicharoon, Richard Hodgett

Multiple Criteria Decision Analysis (MCDA) methods are widely used in various disciplines as a logical solution to a complex decision-making problem. The majority of the research to date has been focused on the development of new MCDA methods for different decision-making challenges. However, given this large number of potential solutions, there is an accessibility challenge in identifying an appropriate method, especially for people who are unfamiliar with them. There has been work which proposed a framework to help select a MCDA method, but the challenge with this is that it requires an understanding of MCDA terminology.

We propose a decision support system to solve such a challenge, utilizing artificial intelligence in the form of a large language model (LLM) as an interface between the decision-maker and a framework for the selection of MCDA methods from a pool of 56 potential options. The decision-maker would briefly describe their decision-making problem in a natural language format which would then undergo a LLM reasoning process to extract the necessary information and align them with the choice framework model. It will identify and interact with decision-makers to provide and justify a method that is most appropriate to their problem.

1 - Generative AI For OR People: Disruptor, Enabler Or Distraction?

Making An Impact, Michael Lindahl

Large Language Models (LLMs) have taken the world by storm since the release of ChatGPT. These models can work with large amounts of unstructured data, such as text and images. Their output is easy to understand, but they cannot reason and apply logic. On the other hand, Mathematical Optimization Models require structured and complete data but provide optimal output. However, it can often be a challenge to collect the necessary data in an organization and ensure that users can interact with the final application and understand the output. Can these very different models complement each other when we build OR applications? This 90' session will be led by Michael Lindahl. Michael has been building OR-powered decision applications across different industries for more than 10 years. Since the release of ChatGPT, he has been exploring the synergies between simple optimization and LLMs by building the application www.findgaven.ai on top of their API's. Michael will give an introduction to large language models, explaining their capabilities, the pitfalls, and how they can fit into the OR toolbox. This will lead to discussion, with the audience invited to share not only their questions but also their own experiences, aspirations, and concerns.

1 - Defending the Weighted Geometric Mean Aggregation

Pavel Janda, Daniele Chiffi

The weighted geometric mean (WGT) is a commonly discussed procedure for aggregating judgements in multicriteria decision analysis (MDA) and social epistemology, but it has drawbacks. We combine MDA and social epistemology results to defend the ratio judgements aggregation with the WGT. We argue that aggregation with the WGT overcomes many drawbacks if one aggregates ratio judgements instead of absolute judgements. We use an axiomatic approach to argue that one should aggregate ratio judgements (we especially favour odds) instead of absolute judgements for the following reasons. First, the mathematical structure underlying ratio judgements (and their aggregation with the WGT) allows one to satisfy many desirable axioms that - for absolute judgements - lead to undesirable results. For example, we avoid dictatorial decisions, can weigh experts' judgements according to their expertise, and satisfy unanimity. Secondly, aggregation of ratio judgements is better suited to control and mitigate possible manipulations such as rank reversal than aggregation of absolute judgements, which can improve legal and ethical aspects of decisions. We present an intuitive sufficient condition that, if met, avoids any rank reversal by adding or deleting alternatives. We also present a sufficient condition for preventing rank reversal for marginalisation, roughly speaking, when initially separated alternatives are transformed into a single alternative using disjunction.

2 - A Fuzzy Logic Application to Manage Costs in Large-Scale Projects

Rubina Canesi, Chiara D'Alpaos

In large-scale projects, such as transport infrastructure developments, the cost planning phase stands out as one of the most crucial for the project success. Cost and time overruns, during the construction phase, are often the cause of project failure. A meticulous, conscious, and accurate ex-ante analysis of cost and time assessment can greatly contribute to the efficient and effective completion of a project. Various approaches have been developed to estimate and mitigate cost overruns. Such mitigation is subject to careful analysis of project risks, encompassing construction, environmental, social acceptance, and market risks. In this contribution, we propose the implementation of the risk assessment tool suggested by the National Anti-Corruption Authority (ANAC) using fuzzy logic to enhance its effectiveness. This application can provide public authorities with a tool to assess expected risk during the design and implementation phases of the project. By associating probability matrices of occurrence and expected impact with fuzzy prioritizations, this tool can facilitate risk assessment and management during the design and construction phases as well as consensus creation process.

creates targeted action plans for specific improvements. This data-driven approach fosters accurate and reliable evaluations, promoting continuous improvement in Colombian engineering education. Ultimately, DEA and Bootstrap offer a robust and objective method to optimize educational efficiency, identify best practices, and define achievable learning objectives.

2 - Analysis of citation impact of ORMS journals by DEA models

Josef Jablonsky

Performance and citation impact of scientific journals are measured by traditional metrics such as impact factor, article influence score, journal citation indicator, and others. While the impact factor is based on the total number of citations and does not reflect the quality of journals cited, the article influence score considers the past importance of the citing journals. This paper aims to analyze the possibility of measuring the performance of journals by data envelopment analysis (DEA) models. We applied traditional radial and SBM DEA models with weight restrictions where the outputs of the models are the citation counts from Q1 to Q4 categories and other journals according to the impact factor. This basic model is extended by considering the impact factor of the journals from the previous year as one of the inputs of the model. The results of the study are illustrated in the set of 80 journals from the Web of Science category Operational Research and Management Science (ORMS). The dataset for the study was obtained from the Journal Citation Reports in the period from 2017 until 2022. The relative efficiency scores and the ranking of the journals obtained by the models are presented and compared with traditional metrics.

3 - Performance Trends in Educational Equity in the OECD: An International Assessment using Malmquist Indices

Giovanna D'Inverno, Cristina Polo, Gabriela Sicilia, Rosa Simancas

In this research we assess the performance trends of the OECD education systems in terms of equity. To do that, we apply a novel methodology that combines a robust conditional Benefit of the Doubt (BoD) model with Malmquist indexes. This approach allows us to compare the performance of education systems over time based on a comprehensive indicator, without losing its multidimensional nature and respecting the different priorities and peculiarities of each educational system, making the comparison between countries fairer. This assessment enables us to identify which educational systems have improved their performance in equity over time (best practices) and which countries have a greater room for improvement. In addition, we assess the impact of different institutional factors and educational policies (e.g., early tracking, school choice systems, ability grouping and retention grade practices, scholarship and voucher programs, among others) on equity performance, in order to identify effective interventions to promote more equitable education systems.

Stochastic lot-sizing problems

Stream: Lot Sizing, Lot Scheduling and Production Planning
Invited session

Chair: Martin Grunow

1 - A robust model for the lot-sizing problem with uncertain demands

Agostinho Agra

We consider the lot-sizing problem with set-ups where the demands are uncertain. The demand in each time period is assumed to belong to an interval. We propose a novel approach to evaluate the inventory

costs where between two consecutive production periods, the adversary chooses to set the demand either to its higher value or to its lower value in order to maximize the inventory (holding or backlog) costs. A mixed-integer model is devised and a column-and-row generation algorithm is proposed. Computational tests based on random generated instances are conducted to evaluate the model, the decomposition algorithm, and compare the structure of the solutions from the robust model with those from the deterministic model.

2 - Stochastic programming for responsive production operations under uncertain disruptions

Arsham Atashi Khoei, Vaggelis Giannikas

Manufacturing systems aim to be streamlined and produce innovative and high-quality products just in time to meet consumer needs. Just-in-time manufacturing processes have suffered significantly from disruptions in the supply chain, demand uncertainty, shop floor break downs, product quality failures, etc. To be responsive to all possible disruption scenarios in the future, first we need to recognize and assess the consequences of any changes we will have to make under these disruptions. Then, by use of an optimization method, we need to minimize the impact of these unexpected disturbances. For this purpose, we observe all these disruptions under several possible scenarios and develop a stochastic programming formulation. The objective function of this formulation minimises the total expected costs of a production operation that consists of production costs, inventory holding costs, inspection costs, and the penalty costs for the uncompleted orders. The uncertainties in this formulation stem from machine break downs, product quality loss, and demand fluctuations. Since the developed stochastic quadratic integer formulation is not efficient to solve large instances with a large set of scenarios, we study a heuristic solution approach based on scenario reduction logic. The generated optimization tool will support people in production industries to observe the consequences of different scenarios with alternative solutions and to make the best decision in terms of imposed costs.

3 - A hybrid approach for sales and operations planning under demand and supply uncertainty

Thorsten Greil, Martin Grunow

Sales and operations planning (S&OP) problems are rarely addressed with stochastic methodologies since available real-world data often limits applicability. We address this issue in a case study with a global electronics manufacturer and develop a hybrid approach to an S&OP problem under demand and supply uncertainty for multiple products. Decisions cover the full range of S&OP, i.e. raw materials, production, transport to distribution centers, inventories, and demand fulfillment. To tackle demand uncertainty, we use scenario-based two-stage stochastic programming. Scenarios are created with readily available data such as point forecasts and correlated forecast errors. To overcome data limitations, we employ shrinkage covariance estimation. Furthermore, we address supply lead time uncertainty with parametric cost function approximation for a central raw material's stock level. We thus capture the extent to which raw material safety stock should be altered beyond the level implied by our demand-based stochastic program. We chose this approach instead of extending our scenarios since companies tend to have no regular lead time review process, hardly store related data in a structured way, and do not forecast lead time. Another reason is the higher computational burden if we extend scenarios by supply uncertainty. While conducting out-of-sample rolling horizon evaluation, we optimize the parametrization online and compare our hybrid approach to its deterministic counterparts.

4 - Multi-stage Stochastic Programming for Lot Sizing with Perishables under Demand Substitution

Bahar Cennet Okumusoglu, Martin Grunow

For perishable products, it is common industry practice to resort to substitution in case of stock-outs. In this work, we investigate the stochastic capacitated lot-sizing problem for perishable products under dynamic demand substitution. We consider a single-echelon lot-sizing setting with multiple products that require the same limited production capacity. We assume that products have fixed shelf-lives and constant production lead times. To represent real-life conditions, we allow for correlated product demands that evolve dynamically over time. We

formulate this problem as a multi-stage stochastic program and propose a scenario tree approximation. We solve the resulting problem in a rolling horizon procedure. Our preliminary numerical results demonstrate the value of our proposed formulation for production and inventory planning of perishables and the value of substitution.

1 - Long-term Forecasting of Seasonal Goods using De-biased Expert Judgment: Beyond the Pandemic

Arnd Huchzermeier

The problem of forecasting demand for seasonal products became even more challenging for retailers amid the Covid-19 pandemic. They are now faced with the difficult task of forecasting demand in the "new normal". On the one hand, the pandemic's future trajectory is hard to predict. On the other hand, an increase in supply constraints forces retailers to confirm orders several seasons in advance. Given this increased uncertainty in future demand, we develop a forecasting model that combines de-biased expert judgment to utilize their knowledge of shifts in consumer behavior, the effects of inflation and other global factors on product demand, and statistical methods well suited for extrapolating repeated patterns from the past. Using data from a premium bicycle manufacturer, we show that accurate demand forecasts for the next three years can be obtained by integrating experts' estimates of the category growth rate with a seasonal decomposition of the pre-pandemic demand curve. Our method yields a forecast error (MAPE) of 18.05%, on average, on data from early 2022. Moreover, our integrated human-algorithm forecasts perform better than statistical time-series forecasts, indicating that experts play a decisive role in predicting demand for seasonal products during and after the pandemic.

2 - The Shift from Immediate Discount Coupons to Reward Points Coupons: Does It Promote Short- and Long-Term Buying?

Yordan Sölter, Arnd Huchzermeier, Christian Schlereth

Loyalty programs are widely popular amongst firms and consumers. These programs usually offer reward points for purchases that can be redeemed at the firm to pay for future transactions. Firms may use reward points as an incentive in promotions instead of offering a price discount. Offering reward points as incentive in a promotion may address challenges associated with price discounts, such as the direct margin impact and failing to boost repeat purchases. In using reward points from their loyalty program as an incentive in promotions (reward points coupons) instead of immediate discounts (price discount coupons), firms seek to optimize the gross profit from the promotion by reducing costs and strengthening repeat purchase behavior. We compared both coupons in a field experiment with a retailer, finding: (i) Both boost short-term sales significantly. (ii) Compared to immediate discount coupons, future-credit coupons cut redemption revenues by 50%, despite higher average transaction spends, due to fewer redemptions. Despite cost benefits, they yield less profit than immediate discounts. (iii) Redemption of future-credit coupons fails to increase total spend or repeat purchases post-promotion in comparison to the redemption of an immediate discount coupon. Retailers' hopes for loyalty points over immediate discounts in promotions don't pan out.

3 - Bespoke Direct Marketing Optimization

Philipp Pithan, Arnd Huchzermeier

Firm growth and profitability are typically achieved through new customer acquisition and loyal customer retention, often relying on non-discriminatory mass marketing. Given the rise of customer databases and firms' natural desire to build lasting customer relationships, retailers increasingly employ direct marketing measures. Yet the associated marketing campaigns tend to be wasteful and myopic, leaving a vast potential untapped. Bespoke Direct Marketing Optimization (BDMO) comprises (i) campaign selection, (ii) campaign sequencing, and (iii) the targeting of (sub)segments for (re)activation while considering multiple objectives. We propose an optimization model that solves these decisions simultaneously while adhering to multiple business constraints, incorporating actual customer buying behavior, and accounting for the multi-period customer migration, which, despite its major implications, is often ignored by other DMO models. We also describe a heuristic that can be applied to larger problem instances. We dramatically reduce the complexity and runtime of the optimization problems while still obtaining nearly optimal results. Using a real-world planning problem, we perform a numerical study for testing and benchmarking. There is a limit to the performance effects of increasing the budget for direct marketing models; any improvement beyond that limit is possible only with models and/or measures that are more bespoke.

4 - The Analytical Edge in Circular Economy: Predictive Analytics for Reusable Packaging Success

Alexander Niclas Popovic, Arnd Huchzermeier

Driven by environmental pollution concerns and legislative pressure, an increasing number of Industry 5.0 initiatives and impact startups have recently emerged, focusing on establishing circular economy business models. One emerging industry is combating plastic waste through innovative reusable packaging systems.

In this study, we examine the case of the German startup Vytal, which offers a deposit-free reusable packaging system for take-out food, utilizing serialized containers. We develop a forecasting framework to estimate the distribution of net demand, consisting of container issues and returns. Accurate net demand forecasts are critical for optimizing asset utilization and inventory management of reusables. We propose a forecasting framework based on a pool of distributed lag models for estimating container issues and returns. Each model exploits the relationship between container issues and returns to make accurate predictions, and we combine them into an "optimal" model using an adaptive Markov Chain Monte Carlo algorithm. Furthermore, we examine several extensions of our basic model and analyze the benefits of including additional covariates, as well as leveraging cross-location forecasts into our model.

We use a unique dataset from Vytal to demonstrate that our proposed forecasting framework outperforms existing models and algorithms from both the literature and our case company in terms of forecast accuracy and computational inference efficiency.

widely explored and continues to be an active area of research. Two main directions could be revealed. Investor-centric studies seek to directly link ESG to CFP using benchmarks and adopting a portfolio accordingly, while corporate-focused research explores different elements of performance like innovation and operational efficiency to understand the impact of ESG initiatives on CFP. These studies commonly employ correlation analysis, mediating factors, or regression analysis to disclose those patterns. Notably, some studies employ Data Envelopment Analysis (DEA) to assess corporate efficiency by minimizing their resources and maximizing ESG. We contribute to this field by using a benefit-of-the-doubt (BoD) model based on the DEA, which is used to calculate a composite indicator of ESG for manufacturing corporates. Then, in the second stage of this model the panel regression is used to identify elements of CFP and their significance for the ESG outcome. The results of corporate ESG efficiency is discussed in a view of corporate operating country, region and development level. The research has received funding from the Research Council of Lithuania (LMTLT), agreement No. S-PD-22-23.

2 - Exploring aspects of risk and sustainability in portfolio composition and Assets and Liabilities Management (ALM) for a Brazilian fintech

Fernando Luiz Pereira de Oliveira, Carolina Vieira, André Robine, Gustavo Souza

This work presents a case study focusing on the importance of Assets and Liabilities Management (ALM) in a complex economic scenario, of a Brazilian fintech company with a significant cash flow of 27 billion BRL per year. Applying methods from modern portfolio theory, multivariate analysis and data mining, we identify the classifying variables that affect credit risk and liquidity for this company and demonstrate how through a data-oriented risk profile one can optimize profitability with strategies that nonetheless comply with United Nations' Sustainable Development Goals (SDGs). Specifically, we approach the adequacy of the company's ALM strategy to SDG 8 (Decent Work and Economic Growth), which is of particular importance in the Brazilian context and Latin America in general.

3 - Reputation risk mitigation in investment strategies

Alexandra Moura, Carlos Oliveira

We consider an investment model in which a firm decides to invest in the market, taking into account its future revenue and the possible occurrence of adverse events that may impact its reputation. The firm can buy an insurance contract at the investment time to mitigate reputation risk. The firm decides when to enter the market and the insurance strategy that maximizes its value. We consider three types of insurance contracts and different premium principles. We provide analytical conditions for the optimum and study several numerical examples. Results show that the firm's optimal strategy depends on the risk size, the firm's risk aversion, and the insurance premium.

1 - Benders decomposition for robust and congested partial set covering location

Alice Calamita, Ivana Ljubic, Laura Palagi

We present the congested facility location problem with partial coverage under the assumption of uncertain customer demand. First, we formulate the deterministic problem and its robust counterpart as mixed-integer quadratic problems. Second, since the size of the robust counterpart grows with the number of customers, which could be significant

in real-world contexts, we investigate the use of Benders decomposition to effectively reduce the number of variables by projecting out of the master problem all the variables dependent on the number of customers. We discuss single-tree and multi-tree Benders approaches and introduce a perturbation technique to deal with the degeneracy of the Benders subproblem efficiently. Our tailored Benders approaches outperform the state-of-the-art solver Gurobi on adapted instances from the literature.

2 - On mines, flows and investments: a new algorithm for the precedence constrained continuous knapsack problem.

Valerio Dose, Fabio Furini, Marco Locatelli

Imagine a student who must obtain a certain amount of credits to graduate and needs to choose which courses to take. Naturally, they would like some of them more than others, but it may be the case that to attend a course they are required to complete also some of the less preferred ones. Thus, what is the best plan to employ?

This is an example of a precedence constrained knapsack problem in combinatorial optimization. In this talk we will introduce some continuous relaxations of this problem which have applications in the mining industry, and can be suitably used to model other investment planning problems.

We will present a new algorithm to compute a solution, which is devised studying the behavior of the classical primal simplex algorithm when applied to the LP formulation. This reveals one of the very few examples of a simplex algorithm with an underlying combinatorial structure.

3 - Critical infrastructures location via submodular maximization

Fabio Furini, Stefano Coniglio, Ivana Ljubic

We study a family of discrete optimization problems asking for the maximization of the expected value of a concave, strictly increasing, and differentiable function composed with a set-union operator. The expected value is computed concerning a set of coefficients taking values from a discrete set of scenarios. The function models the utility function of the decision maker, while the set-union operator models a covering relationship between two ground sets, a set of items, and a set of metaitems. This problem and it can be modeled as a mixed integer nonlinear program involving binary decision variables associated with the items and metaitems. Its goal is to find a subset of metaitems that maximizes the total utility corresponding to the items it covers. It has applications to, among others, maximal covering, location of critical infrastructures and influence maximization problems.

EV users view charging more as an opportunity than as an indispensable need. They are inflexible in their parking duration, which depends on their on-site activities, but they are flexible in terms of their energy demand, and choose the option that maximizes their welfare, i.e., their utility minus their cost of charging. We formulate the optimal price menu design problem of a profit maximizing CSO as a mixed integer linear programming problem, and we compare against the outcome of social welfare maximization. We further account for the provision of demand response by the CSO, i.e., lowering its power consumption for a certain period given a certain price for remuneration, by adjusting the price menu (in real time), to incent EV users to choose lower power rates. Our numerical demonstrations provide useful insights on the construction of the optimal price menu.

2 - An optimization-simulation model for locating an electric vehicle charging station using clean energy sources..

Zaira Ramirez, Aida Huerta-Barrientos, Alma Elia Vera-Morales

Nowadays, the countries of the European Union contemplate an energy mix that includes a high percentage of renewable energies, favorable for the charging of electric vehicles and for the reduction of polluting gases. Unfortunately, the energy used to charge an electric vehicle in Mexico comes from a highly polluting energy mix that primarily uses fossil fuels, which generates 18% of CO₂ emissions. Multiple authors suggest that electric vehicle charging should be done using renewable energy sources. In Mexico, there are no sustainable alternative energy sources that allow for the charging of electric vehicles, compromising the sustainability of this technology and its development. This research focuses on the optimal location, through an optimization-simulation model, of a charging station that transforms energy obtained from clean sources, which will allow meeting the demand for charging electric vehicles, leveraging pet waste in the context of parks in Mexico City. First, the Factor Method was used to calculate the optimal location of charging for electric vehicles. Second, the optimal location was implemented based on an agent-based simulation approach using Anylogic™ software to analyze the dynamics of electric vehicles and pets. Third, simulation scenarios were built considering an increase on demand. The results obtained support decision-making regarding the implementation of the charger in parks, demonstrating the utilization of organic waste generated by pets.

3 - Charging Infrastructure Optimization for Independent Electric Vehicle Routing: A Case Study in Norway

Jesper Bang Mikkelsen, Remy Spliet

Conventional vehicles are characterized by long and reliable driving ranges and are furthermore supported by a well-established refueling infrastructure. Therefore, vehicle refueling has traditionally been ignored in vehicle routing problems in the literature. However, with the adoption of electric vehicles (EVs) in distribution fleets, a new extension to the vehicle routing literature has emerged. Today, EVs are limited by short driving ranges and, especially for heavy-duty EVs, the infrastructure of charging stations is still sparse. Hence, much effort has been made in the literature to develop complex routing models that integrate routing and refueling decisions for EVs. However, with a sufficient infrastructure of charging stations, vehicle refueling may yet again be ignored, such that solutions for traditional vehicle routing problems are feasible for EVs.

In this study, we introduce the Charger Location Problem (CLP), which aims to determine charging infrastructure requirements for supporting charger independent EV routing. We present four variations of the CLP based on how frequently recharging is allowed and the number of trips considered. Through a case study in Norway, we demonstrate the significant impact of strategically locating charging stations along highways. Our findings underscore the importance of proactive infrastructure planning in facilitating the transition to independent EV routing, offering insights for policymakers and fleet operators.

1 - Robustness and Resilience Evaluation Method for High-Speed Railway Timetable

Peiran Han, Lingyun Meng, Xiaojie Luan, Nikola Bešinović, Jianrui Miao, Yihui Wang, Zhengwen Liao

The railway system frequently encounters abnormal events such as disturbances and disruptions, highlighting the importance of evaluating the resistance capability of train timetables. However, there is limited research focusing on their boundaries and dynamics. This study contributes to two main aspects: Firstly, to evaluate the functionality of robustness, we construct a delay propagation network to measure several indicators (heterogeneity, slack time, and delay). Based on this methodology, we can clarify the generation and operating mechanism of robustness. Secondly, to quantify the resilience of timetables with different headways, we employ a heuristic approach to obtain saturated timetables, which serve as input for a rescheduling simulation engine. We establish several resilience metrics and utilize Data Envelopment Analysis (DEA) to evaluate the comparative performance of various timetables across different disruption scenarios. Finally, we apply this evaluation framework to the Beijing-Shanghai HSR line. The proposed method provides railway operators with a systematic approach to assess and enhance train timetables, thereby guiding decision-making processes and contributing to the development of more robust and resilient railway operations.

2 - Delay cascading dominates large-scale disruptions in transport

Debabrata Panja

The dynamical intertwining of many heterogeneous operational elements, agents and locations are oft-cited generic factors to make myriad socio-technical systems such as supply chains, (inter) national trade and human mobility, prone to large-scale disruptions. These disruptions are emergent phenomena, and their underlying causes are endogenous, stemming from the systems' operational planning. We demonstrate this by analysing spreading of delays on the Dutch train network: the emergence of large-scale disruptions rests on the dynamic interdependencies among multiple 'layers' of operational elements (services, rolling stock and crew). The interdependencies provide pathways for delay cascading, which gets activated when, constrained by local unavailability of on-time resources, already-delayed ones are used to operate new services. Cascading locally amplifies delays, which in turn get transported over the network to give rise to new constraints elsewhere.

Systemically building in (temporal) buffers can arrest delay propagation in socio-technical systems. However, the general tendency in Operations Research, reinforced by competitive pressures, is to myopically in reduced buffers. Ironically, such optimisations can push a system to the proverbial "cliff edge", increasing its fragility to large-scale disruptions. We therefore draw attention to the proposal that any welfare function that a system operator seeks to optimise should contain a measure of resilience.

3 - Optimization model and algorithm of train timetable structure for train timetable resilience enhancement

Ruyue Zhao, Lingyun Meng, Xiaojie Luan, Zhengwen Liao

For fully meeting the transportation demand, railway network has gradually become density and busy, making a close coupling relationship between trains. However, this leads to the severe delay propagation between trains, when disturbance occurs. And train timetable resilience gives timetable the ability to resist disturbances. The key

to improve the resilience is to reduce the propagation of train delay, and the structure of train timetable plays a decisive role in this regard. And heterogeneity of train timetable is a key factor. When the heterogeneity is high, the timetable structure is complicated, and once the disturbance occurs, it will constitute a complex delay propagation chain between trains. So, it is necessary to improve the resilience by optimization of timetable structure. In this paper, we study the optimization of timetable structure towards the improvement of resilience. And we take the maximum train timetable resilience as the objective function, construct an optimization model of train timetable structure and design a two-stage solution algorithm. Besides, the results of case studies show that the train timetable structure optimization model and algorithm we proposed is effective. And we further verify by simulation that timetable structure optimization method has a significant effect on improving the resilience.

4 - A multiobjective model for adaptable train unit scheduling in normal and emergent conditions

Zhiyuan Lin, David Watling

Train unit scheduling optimisation (TUSO) involves allocating train unit vehicles to fulfil timetabled trips, with the option to couple or decouple units to allow flexible rolling stock configurations for a train. TUSO typically balances two conflicting objectives by Pareto multiobjective (MO) optimisation: meeting passenger demand and minimising rolling stock use. However, certain emergencies, eg adverse weather or signal failure, require a significantly reduced timetable, making it challenging to meet full passenger demand with fewer services. In this case, a different rule is used that as long as adjusted demand is met, a solution is acceptable regardless of other objectives. This is beyond the capability of Pareto methods, as setting a large weight on demand is oversimplification. Pareto methods also face challenges in decision making involving uncertainty/fuzziness. Experts may find real-time selection of frontier solutions impractical. We propose a novel MO TUSO model for both normal and emergency cases on a synthetic TUSO instance. By tuning its parameters, the model can switch between the two, or intermediate states. It provides a probabilistic metric for gauging solution desirability across a continuum, as seen by different experts/rules via tuned parameters, instead of binary choices in efficient and inefficient options. This is valuable for uncertainty or real-time scenarios where the 'best' solution relies on complex factors, eg hierarchically prioritising demand.

1 - Ruin-and-recreate heuristics for the fixed charge transportation problem

Gavin Le Roux, Stephan Visagie

Recently, the literature has become too focused on variations of the fixed charge transportation problem (FCTP), such as solid, step, capacitated or multi-stage, despite a significant number of gaps remaining in the research for pure FCTPs. The research presented is focused on developing ruin-and-recreate (R&R) heuristics specifically for pure FCTPs, which have not been implemented before. R&R heuristics are new methods applied to combinatorial optimisation problems (specifically vehicle routing problems) in which a solution is destructed (possibly reaching an infeasible solution) and rebuilt in an intelligent manner to maintain feasibility. This is done repeatedly until a desired solution is reached.

Four ruin methods utilising the tree structure of FCTP basic feasible solutions, seven recreate methods divided into single-cell and multi-cell heuristics, and various metrics to determine entering and leaving variables in each iteration of a ruin or recreate method, are developed. Different variations of the algorithms are executed on a set of existing and newly generated benchmarks for algorithmic comparisons. Different characteristics of a problem, such as the problem size, fixed charge to variable cost ratio, average units supplied/demanded and arc density, are reported on to determine strong performing algorithms in given situations. Lastly, the convergence of the algorithms as well as the trade-off between solution quality and computational time are explored.

2 - Two Level Time Minimizing Transportation Problem

Sonia Singh, Ankit Khandelwal

For a given time minimizing transportation problem comprising of m sources and n destinations, the set of m sources is to be optimally partitioned into two mutually disjoint subsets L_1 and L_2 where, L_1 contains m_1 sources called Level-I sources and L_2 contains the remaining $(m - m_1)$ sources termed as Level-II sources. First, the Level-I decision maker sends the shipment from Level-I sources to partially meet the demand of destinations. Later, Level-II decision maker sends the material from the Level-II sources to meet the left over demand of the destinations. A finite number of mixed 0-1 programming problems are solved to judiciously generate a subset of partitions of the set of m sources. The aim of this study is to find an optimal partition of the set of m sources such that the sum of times of transportation in the Level-I and Level-II shipments is the minimum. The proposed algorithm to find the global minimizer has been successfully run on a variety of randomly generated test problems differing in input data.

3 - Enhancing Emergency Response Efficiency via Deep Reinforcement Learning: A Novel Model for Dynamic Dispatching

Felix Rauschert, Matthias Ribesmeier, Pascal Kerschke

Emergency Medical Services (EMS) are essential for providing timely pre-hospital care. Efficient EMS dispatching, a critical yet complex decision-making process, involves not just quick responses to emergency calls but also optimal resource allocation amidst unpredictable demands. While traditional dispatch strategies typically prioritize sending the nearest vehicle, research has shown this approach does not yield the best outcomes. We introduce a comprehensive solution that integrates factors like scalability, uncertainties, dynamic environments, and adaptive strategies, thereby enhancing the EMS system's ability to respond more effectively and efficiently.

We propose a novel approach using Deep Reinforcement Learning (DRL) to refine EMS response efficiency. By integrating key metrics such as emergency severity and response time, we offer a strategic decision-making framework that significantly improves operational outcomes. Utilizing publicly available data from San Francisco, we highlight our DRL model's effectiveness in surpassing traditional dispatching methods. Our approach uniquely leverages a larger state-action space for DRL and incorporates crucial performance indicators, making EMS deployment more nuanced and efficient than in previous studies. This results in faster, more effective incident responses than traditional strategies, showcasing the potential of advanced machine learning in emergency dispatch optimization.

4 - Two-stage approach for rail freight terminal scheduling with mainline passenger traffic interaction

Daniel Haalboom, Nikola Bešinović

In the European rail network, infrastructural limitations of terminals pose critical bottlenecks for the scheduling of rail freight services. In addition, passenger traffic on mainlines leading up to the terminals puts additional constraints on efficient rail freight scheduling possibilities. Thus, integrating terminal activities and mainline operations in a rail freight scheduling approach could significantly improve infrastructure usage. However, interactions between freight and passenger traffic in freight terminal scheduling have received little attention in scientific literature so far. We propose a two-stage approach to schedule rail freight services in a freight network with interacting mainline passenger services. The focus is on short-term scheduling, and thus

freight trains are considered and included in the schedule as requests arrive. In the first stage, we use a dynamic infrastructure cost structure to schedule successive trains. In the second stage, we apply the initial solution from the first stage for a subsequent global optimization of the requested freight train services. The applied two-stage optimisation approach minimises the deviation from requested train paths and allows determination of critical infrastructure elements for each included subset of trains. This model improves the quality of freight train scheduling and offers a better inclusion of yards leading up to the terminals into the train scheduling.

1 - E-Truck Fleet and Infrastructure Co-design via Joint Optimization and Agent-based Simulation

Juan Pablo Bertucci

In the immediate advent of zero-emission zones fleet operators are transitioning to electric fleets. To maintain their current operations, a clear understanding of the charging infrastructure needed and its relationship to existing power grid limitations and fleet schedules is needed. In this context, we optimize the charging infrastructure and the routing and charging schedules for a logistic distribution network in a joint fashion, and validate our results via agent-based simulations. Specifically, we first cast the joint infrastructure design and operational scheduling problem as a mixed-integer linear program. Second, we devise an agent-based model that serves as a virtual experimental replica to test different design and operation solutions. Finally, we run experiments where we compare rule-based with optimized design and operation strategies in key operational metrics and power requirements in a case-study of The Netherlands. The results indicate that having local vehicle charging rules helps decrease the impact of uncertainties in consumption, thus enhancing logistics reliability. However, central coordination leads to more cost-efficient solutions and less stringent power requirements.

2 - Estimating greenhouse gas emissions of electric delivery trucks

Tugce Yuksel, Mert Ozcelik, Sinan Yildirim

Previous literature show that emission benefits of electric passenger vehicles can vary a lot when regional differences such as grid mix, ambient temperature, patterns of vehicle miles travelled and driving profiles are considered. In this study, we propose a simulation model which can be used to extend the analysis to estimate GHG emissions of electric delivery trucks considering all these differences. We first develop an energy consumption model for delivery trucks based on real world usage data. Our model can estimate energy consumption per unit distance using average speed, ambient temperature, trip duration and acceleration characteristics. We then create a simulation framework which can be used to estimate the energy consumption from a fleet for a certain timeframe and calculate the emissions due to charging. Our framework can incorporate regional differences and it can create charging profiles (time and duration of charging) under different strategies such as immediate charging after the final trip, convenience charging or delayed charging. The results are combined with emissions factors from regional electricity grid to estimate use-phase emissions due to charging. As a case study, we use our simulation framework to quantify the effect of ambient temperature on CO₂ emissions of electric delivery trucks in the United States and present the regional implications.

3 - A Stochastic Shared Car Relocation Problem to Optimize Long Term Strategic Inventory Decisions

Mehmet Serdar Erdogan

In one-way flexible car-sharing systems, customers can drop-off the rented car at any location inside the operation area of the company and price of the rental is proportional to distance or duration of the rental. Rules of this system result in a supply and demand imbalance since supply of each zone changes dynamically. High-demand zones tend to have lower supply, and low-demand zones tend to have higher supply. Therefore, car-sharing companies relocate the cars between zones to match the supply and demand. This relocation process is costly and requires optimization for a profitable business. In this study, we formulate a two-stage stochastic programming model to optimize the relocation decisions in a dynamic one-way flexible car-sharing system. The model decides inventory levels of each zone at the beginning of each time period, number of cars to be relocated between each pair of zones, and unsatisfied requests at each zone to minimize total cost of relocation and lost sales. This model is very effective for small and average size instances. To solve the large instances, we developed an approximate clustering method where zones are clustered into multiple clusters. This approximate clustering method can solve instances up to 40 zones and 36 time periods. To enhance the implementation, we have also proposed an extended model where the staff movement was taken into account. Results show that inventory levels at each zone tend to reach a steady-state.

4 - A bicycle rebalancing model to minimize cost of operations and unmet demand in a docked network

Aliki Poulisi, Amalia I. Nikolopoulou, Konstantinos Gkiotsalitis, Konstantinos Kepaptsoglou

Bicycle sharing systems have the potential to significantly alleviate traffic congestion and minimize demand for parking spaces in urban centers. One critical factor influencing the success of a bicycle sharing system is the effectiveness of rebalancing operations. These operations involve restoring the number of bicycles at each station to its expected demand through pickup and delivery activities performed by trucks. The Static Docked Bicycle Rebalancing Problem (SBRP) focuses on determining a cost-effective sequence of visited stations for a truck, along with the corresponding quantity of bicycles to be picked up or delivered at each station. Deviating from past studies, we propose a new formulation for the SBRP problem which minimizes the cost of rebalancing operations, while factoring in the cost of unmet passenger demand. The developed mathematical model is a mixed-integer nonlinear program, which is reformulated as a mixed-integer linear program. Then, our study introduces an exact branch-and-cut algorithm for addressing the SBRP and presents the results of computational tests. Lazy constraints and valid inequalities are introduced to improve performance and reduce computational time. The experimental findings demonstrate that we can solve to global optimality instances with up to 20 stations. A construction heuristic (nearest neighbor) is also introduced to provide a warm start to the branch-and-cut search, resulting in a more effective search of the solution space.

1 - Real options under ambiguity with rare events

Benoit Chevalier-Roignant, Andrianos Tsekrekos, Athanasios Yannacopoulos

We consider a real-options problem in which the underlying project value follows a geometric or exponential Levy process, capturing rare events besides continuous fluctuations. Such rare events lead to ambiguity because of inconclusive empirical data or market incompleteness. We use ambiguity theory—leveraging the notion of variational preferences and $\$g\$-expectations—to pin down for the general case a pricing kernel under which to value real options and derive the firm's optimal exercise strategy under this kernel. We also provide sufficient conditions for the optimality of a threshold policy in the general case. For the case with multi-priors preferences, we obtain explicit expressions for the optimal investment threshold, expected investment time, and value function and prove comparative statics to assess analytically the effect of small jumps on these. Closed-form expressions are not available for multipliers preferences, but we provide approximate solutions for the cases with negligible and deep ambiguity. Rare events, which are priced under ambiguity aversion, generally lead to a higher investment threshold, delayed investment and higher option value.$

2 - On the separation of estimation and control in risk-sensitive investment problems under incomplete observation

Sebastien Lleo, Wolfgang Runggaldier

A typical approach to tackle stochastic control problems with partial observation is to separate the control and estimation tasks. However, it is well known that this separation generally fails to deliver an actual optimal solution for risk-sensitive control problems. This paper investigates the separability of a general class of risk-sensitive investment management problems when a finite-dimensional filter exists. We show that the corresponding separated problem, where instead of the unobserved quantities, one considers their conditional filter distribution given the observations, is strictly equivalent to the original control problem. We widen the applicability of the so-called Modified Zakai Equation (MZE) for the study of the separated problem and prove that the MZE simplifies to a PDE in our approach. Furthermore, we derive criteria for separability. We do not solve the separated control problem but note that the existence of a finite-dimensional filter leads to a finite state space for the separated problem. Hence, the difficulty is equivalent to solving a complete observation risk-sensitive problem. Our results have implications for existing risk-sensitive investment management models with partial observations in that they establish their separability. Their implications for future research on new applications is mainly to provide conditions to ensure separability.

3 - Decision criteria under ambiguity for robust portfolio choice given a sample of assets' returns

Eric André

This paper applies axiomatic models of decision under ambiguity to the optimal portfolio choice problem with two objectives: firstly to account for the probabilistic model uncertainty, secondly to take into account the information contained in an observed sample of assets' returns. Especially, a criterion is proposed which is a special case of the Variational Preferences. Restated in the Bayesian statistics notations, it is a regularized optimal problem which explores possible probabilistic models weighted by their likelihood given the observations. Examples and numerical simulations are provided to illustrate its properties, notably its robustness to misspecified models by comparing its performance to the benchmark portfolios of the literature. More generally, this paper aims to show that axiomatic models which have been developed to accommodate attitudes toward ambiguity provide a behavioral justification for aversion to model uncertainty in optimization problems, and lead to practical criteria which take into account the sample information.

4 - Management of adverse events: risk mitigation or exiting?

Carlos Oliveira, Rita Pimentel

In this presentation, we consider a firm that may face sudden decreases in its revenue. Its revenue is modeled by a geometric Brownian motion, and the cumulative effect of negative shocks is modeled by a compound Poisson process. The firm has two options: either to exit the market or to adopt risk mitigation measures to reduce the impact of the revenue

decrease. The firm's option value is modeled as an optimal stopping problem, which we analyze in this presentation. Furthermore, we examine the impact of protective strategies on the firm's option value.

1 - Scheduling of Retrieval Operations in an Automatic Warehouse: Models and Algorithms (Preliminary Exploration)

Runjie Li, Xiangtong Qi

The automatic warehouse discussed in this article is based on a puzzle-based storage (PBS) system with block movement, which allows multiple items in a line to move simultaneously, and simultaneous movement, which allows multiple movements to occur at the same time. PBS is one of the most space-efficient types of storage systems, and the way of block and simultaneous movement makes it more time-efficient. However, retrieving multiple target items from this kind of automatic warehouse has not yet been rigorously studied. In this paper, we present a time-expanded based on mixed integral linear programming (MILP) formulation that aims to minimize the summation time of retrieving multiple target loads. Another objective of minimizing the makespan can also be minimized to serve the objective of summation retrieving time. In addition, constructive algorithms are developed for fast obtaining retrieving plan for multiple target items based on the shortest unimpeded retrieval for some special cases. Experiments show that the proposed formulation can solve small to medium size instances, especially when the storage density is not extremely high. We also conducted experiments to explore the efficiency of the proposed automatic warehouse and demonstrate the utility rate of empty locations.

2 - Integer Linear Programming Model for Sequencing and Storage Assignment Operations in a Multi-Aisle AS/RS With Non-Dedicated Cranes

Edgar E. Córdoba-Sarmiento, Edwin Garavito, Laura Y. Escobar-Rodríguez

In recent years, automatization has taken on a relevant role in the low-skilled operations of different productive sectors. One of the most impacted sectors is logistics, which significantly influences product handling, warehousing, and shipping processes. In this context, Automated Storage and Retrieval Systems, AS/RS, become an ideal solution for logistics warehousing systems. Such implementation allows inventory management based on storage and retrieval orders optimizing the use of available physical space and material handling processes and improving system performance in terms of storage and retrieval times, material flow, energy consumption, operating costs, and other associated variable measurements. Multiple physical and control characteristics make up the global design of an AS/RS, involving the type of system technology, the number of aisles, the rack dimensions, storage and sequencing policies, among others. In this work, we studied sequencing and storage assignment operations in a multi-aisle AS/RS with class-based storage, block sequencing strategy, and non-dedicated cranes. We proposed an Integer Linear Programming model to find the best operation decisions, considering the dynamic behavior of the AS/RS and evaluating some control decisions related to these operations. Our findings showed that the fill grade factor, the size of the classes, and the size of the sequencing block affect the performance of the system in terms of travel time metrics.

3 - Let Customers Scatter the Inventory: A Multi-Objective Storage Location Assignment in Warehouses

Mostafa Bahadornia, Katrien Ramaekers, Kris Braekers, Trijntje Cornelissens

The rapid growth of online retailing necessitates flexible warehouse management strategies to adapt to this evolving landscape. One of the key challenges in this area is to reduce the order-picking travel distance. This travel distance is highly affected by the Storage Location Assignment (SLA) decision, which determines how products are allocated to locations in the warehouse. This study aims to develop a mixed SLA strategy which tries to adopt different SLA strategies to some degree that is tailored to the customer order pattern. To do so, four criteria are defined to assess the SLA state: (a) Scatteredness: increases the accessibility of each Stock Keeping Unit (SKU) by spreading its units through the storage locations. (b) Integrity: avoids collecting a single order-line from multiple locations by keeping sufficient number of each SKU in its storage location(s). (c) Association: stores correlated SKUs close to each other. (d) Depot adjacency: stores high-demand SKUs near the depot(s). To address the dynamic nature of business needs, a data-driven approach is introduced to weigh each criterion. Then, A multi-objective mathematical model, incorporating contextual constraints and these weighted measures, is proposed to optimize the SLA. As the ultimate goal is to reduce the order-picking travel distance, the proposed model and hypothesis will be validated for this goal under various business environments.

4 - Library Logistics Operations: An Analytical Study on Material Handling Processes

Fabio Sgarbossa, Niloofar Jefroy, Daniela Granados, Debjit Roy

The library users' experience depends on the library's performance on their operations. Material handling processes are crucial to improve those library's operations and service levels, assuring books and items availability. Even if a flow of research has flourished into implementing new solutions, e.g. Autonomous Mobile Robots (AMRs), in response to operational challenges that limit library performance, scientific literature still lacks modeling such solutions. Hence, this study aims to investigate such solutions and their impact on improving the overall performance of library logistics operations. With the Trondheim Public Library as a case study, several scenarios are analyzed. We considered two layouts: centralized and decentralized with different modes to transport the materials: manual and AMRs. We modeled the scenarios through Queuing Theory. For manual movements, we used Open Queuing networks (OQN), while scenarios used with AMRs are Semi-open Queuing networks (SOQN). SOQN has shown promising applicability in similar contexts to support the decision-making processes for planning and controlling the material flow. The proposed Queuing networks are validated through simulation. Based on this and varying critical parameters such as flow volume, intensity, variability, library layout, and operational modes, we obtain performance measures to characterize the analyzed scenarios for library logistics operations as well as the advantages and disadvantages.

Learning and pricing

Stream: Pricing and Revenue Management

Invited session

Chair: Michi Nishihara

1 - Good stuff: Matching supply and demand by introducing an opaque product: Pricing, learning, fun.

Laura Sprenkels

In this project we help a retailer increase his revenue and decrease his waste by introducing a new selling strategy. Instead of offering his original, fixed priced assortment, he will additionally sell an 'opaque product' with a dynamic price as he sees fit. As he does not now how his clientele will respond to this new product and its price, we help him to find the right balance between earning (by optimizing his revenue) and learning (by gathering enough information to be able to estimate the effect of the new product). An interesting problem with many mathematical challenges.

2 - AI meets Sustainability: Using Digital Twins to Leverage Reinforcement Learning - Based Dynamic Pricing in Circular Markets under Competition

Rainer Schlosser

Nowadays, customers as well as retailers look for increased sustainability. Recommerce markets - which offer the opportunity to trade-in and resell used products - are constantly growing and help to use resources more efficiently. To manage the additional prices for the trade-in and the resell of used product versions challenges retailers as substitution and cannibalization effects have to be taken into account. An unknown customer behavior as well as competition with other merchants regarding both sales and buying back resources further increases the problem's complexity. Reinforcement learning (RL) algorithms offer the potential to deal with such tasks. However, before being applied in practice, self-learning algorithms need to be tested synthetically to examine whether and which work in different market scenarios. We evaluate and compare different state-of-the-art RL algorithms within a recommerce market simulation framework. We find that RL agents outperform rule-based benchmark strategies in duopoly and oligopoly scenarios. Further, we investigate the competition between RL agents via self-play and study how performance results are affected if more or less information is observable. Using an ablation study, we test the influence of various model parameters and infer managerial insights. Finally, to be able to apply self-learning agents in practice, we show how to calibrate synthetic test environments (digital twins) from data to be used for effective pre-training.

3 - The effects of a financial covenant on optimal capital structure and firm value

Michi Nishihara, Takashi Shibata, Benoit Chevalier-Roignant

This paper develops a capital structure model with a financial covenant that sets an upper limit on a firm's debt-earnings ratio. Shareholders will reduce debt or default when the ratio exceeds the upper limit. In the model, firm value, debt repayment policy, and capital structure are derived explicitly. For low levels of the limit, shareholders prefer to reduce debt every time the ratio exceeds the limit. Then, the covenant removes cost of debt, while it decreases equity value by restricting shareholders. By this trade-off, the covenant can improve firm value. The covenant can also improve firm value by suppressing the leverage ratchet effect and removing the restriction on future debt issuance. With the covenant, the firm can begin with high leverage to take advantage of no cost of debt. The covenant tends to improve firm value for higher bankruptcy cost and volatility, and the additional debt channel can greatly improve firm value for higher growth and tax rates. These results are consistent with empirical evidence and support the optimal contracting hypothesis regarding debt covenants.

1 - Best Practices of Digital Transformation for Managing Large Industrial Maintenance Projects

Dimitrios Emiris

Industrial maintenance projects, known as shutdown projects, are highly impacted by the recent growth of digital transformation (DT) efforts. Technological and systemic advancements, sensors integration, data analytics tools, information systems, etc., are some of the factors constantly affecting and changing the operation of most industrial companies. This work drills down to efficient approaches in DT aspects of major maintenance projects and condenses the on-field experience from a dozen such projects over the past decade. Specifically, it highlights best practices on technological, systemic and managerial actions, such as: (i) the gradual development of knowledge databases to improve project planning efficiency by up to 38%; (ii) digital collaboration techniques to elicit requirements and reduce scope creep by almost 16%; (iii) data analysis from on-board sensors to diagnose the operational condition and proactively identify maintenance needs; (iv) the use of digital maps of industrial plants for optimization of works sequences to respect safety constraints; and (v) the development of digital tools for near-real time collection of progress data from remote sites and diverse stakeholders to quickly update plans, forecast reliably, identify issues and cultivate employee engagement. The presentation of the temporal evolution and development of implemented solutions for each best practice highlights the combinatorial benefits of DT and establishes guidelines for the future.

2 - Exploring and Prioritizing Critical Success Factors (CSFs) in Project Management Utilizing MADM approach and PMBOK guide

Ashkan Keykavoussi, Ahmad Ebrahimi

This article explores Critical Success Factors (CSFs) in project management, focusing on key elements for project success. By analyzing common CSFs such as clear and realistic project objectives and strategies, top management support and commitment, effective project planning and scheduling, stakeholder engagement, effective communication, risk management, optimal resource allocation, a competent and motivated team with clear roles and responsibilities, adaptability to change, and leadership, alongside more specific factors, the research aims to deepen the understanding of the factors that drive project success. Through a comprehensive literature review and utilization of Multi-Attribute Decision Making (MADM) methods, the study provides valuable insights to enhance project outcomes and achieve organizational goals. By ranking and prioritizing these critical factors based on input from experienced project managers and practitioners in the field, using expert judgment and the Project Management Body of Knowledge (PMBOK) guide, the research offers practical recommendations to enhance project performance and ensure successful project delivery. This effort aims to bridge the gap between project management theory and practice, ultimately leading to more effective project results.

3 - Decision model for prioritizing public investment projects in a health service

Luis Quezada, Diego Pozas, Astrid Oddershede, Pedro Palominos

This paper introduces a methodology for prioritizing investment initiatives within a Regional Health Service. The absence of a structured methodology directly impacts the timely delivery of solutions in public health to citizens. Currently, investment priorities lack clear definition and justification, affecting the focus on crucial citizen issues that require prioritization in both the planning and execution of the investment portfolio.

To face this challenge, the Analytic Hierarchy Process (AHP) is employed. The prioritization relies on the judgments of experts and stakeholders engaged in the Health Service. Recognizing the constraints of limited financial resources, a method for scheduling projects over time is also incorporated.

The result of this model is a robust approach that enables the effective prioritization of public investment projects outlined in the portfolio. This, in turn, addresses the needs of citizens in public health with projects that materialize within more limited timelines and are based in criteria justifying the allocation of resources.

4 - Batching and scheduling with OptalCP

Diego Olivier Fernandez Pons

In production optimization for manufacturing, directly scheduling the production lines to fulfil the make-to-order, make-to-stock and inventory needs is usually too computationally demanding. Commonly, the problem is divided into a batching phase that creates production batches and pre-assigns them to orders, and a scheduling phase that assigns the batches to machines while minimizing completion time.

This decomposition is usually difficult to adjust, as a too tight batching phase may result in a solution that is far from optimality or even make the scheduling sub-problem infeasible, when a too loose one will result in a scheduling problem that is too hard.

Scheduling engines have gained popularity for the scheduling phase due to their ability to quickly return solutions of high quality while supporting a large variety of scheduling constraints, when the batching phase is usually done with mixed-integer linear programming.

OptalCP is a state-of-the-art scheduling engine in the lineage of IBM ILOG CP Optimizer, that first started providing a MIP-like experience for scheduling engines (lower bounds, model & run). We have extended it to also solve batching and scheduling problems without decomposition.

client must be covered by a second-level facility, and this, in turn, by a first-level facility. This kind of problem can be identified in several applications as healthcare systems, telecommunication networks or e-commerce. The aim of the proposed model, denoted as SL-MCFLP, is to determine the location and product configuration of second-level facilities in such a way that the overall client satisfaction with respect their coverage is maximized. We propose a mixed integer linear programming formulation, and we introduce several valid inequalities to improve its performance time. In some cases, the number of valid inequalities is exponential and, consequently, separation algorithms are developed. In addition, several variants of a matheuristic approach are introduced.

3 - Downgrading edges in the maximal covering location problem

Marta Baldomero-Naranjo, Jörg Kalcsics, Antonio Manuel Rodríguez-Chia

In this presentation, we tackle the downgrading maximal covering location problem within a network. In this problem, two decisions are made: determining the facility locations and increasing edge lengths to reduce coverage. Two actors with conflicting objectives are involved: a) The location planner aims to maximize the covered demand while anticipating that an attacker will attempt to reduce coverage by increasing the length of the edges. b) The attacker seeks to maximize the demand initially covered by the facilities but left uncovered after the downgrade. To achieve this, they can increase the length of certain edges within a specified budget.

We introduce a bilevel mixed-integer program to formulate the problem, a preprocessing phase, and a matheuristic algorithm to address it. Additionally, computational results are presented to illustrate the potential and limitations of the proposed algorithm.

4 - A robust maximal covering location model considering partial coverage

Esra Karasakal, Burak Köksal, Orhan Karasakal

Maximal Coverage Location Problem (MCLP) attempts to find a pre-determined number of facilities to maximize the number of demand points that can be covered. In MCLP, while all demand points within a critical distance of a facility are completely covered, demand points outside this region are not covered at all. In Partial MCLP (MCLP-P), another critical distance is introduced, which allows coverage between two critical distances, monotonically decreasing with respect to demand points' distance from facilities. In this study, we explore MCLP-P under coverage uncertainty. We utilize a robust optimization framework and introduce an approach to hedge against uncertainty. We present the model and the solution approaches and compare the performance of the proposed solution approaches on randomly generated datasets.

Invited session

Chair: *Esra Karasakal*

1 - Valid inequalities for the capacitated facility location problem with preference constraints

Sophia Wrede, Christina Büsing, Markus Leitner

In the classical capacitated facility location problem (CFLP), a set of facilities needs to be chosen in order to cover the demand of customers. Customers are assigned to any open facility such that the capacity of the facility is not exceeded and the total cost consisting of opening and assignment costs is minimized. However, in many real-world applications customers are not willing to travel to any open facility assigned to them but want to select an open facility according to their preferences. Such deviations can turn feasible solutions for the CFLP infeasible. The capacitated facility location problem with preference constraints (CFLP-PC) takes this behavior into account by assigning customers to their most preferred open facility. In this talk, we focus on two types of cover-based inequalities for the CFLP-PC. The first type corresponds to the classical cover inequalities, which we strengthen by taking advantage of a specific structure arising from the combination of capacities and preference constraints. In the second inequality type, we make use of information on the set of open facilities that arises from covers. We discuss the complexity of the corresponding separation problems and evaluate the performance of the inequalities for two preference types in a computational study.

2 - Multi-product maximal covering second-level facility location problem

Luisa I. Martínez-Merino, Marta Baldomero-Naranjo, Antonio Manuel Rodríguez-Chia

In this work, we consider a hierarchical facility framework consisting in three levels. The first-level is composed by a set of facilities which manufacture certain products, the second-level facilities act as warehouses, and finally, the clients demanding some of these products compose the third-level. The products must be supplied to the clients by using the second-level facilities. It should be noted that, in order to satisfy the customers' demand, there must be a double coverage: the

1 - An integrated Berth Allocation and Quay Crane Assignment Problem with Missed Transshipments Recovery

Baptiste Coutton, Dario Pacino, Alberto Delgado, Ignacio Blanco

Global freight transportation relies heavily on maritime shipping using containers. To avoid congestion and disruptions in supply chains, port terminals need to plan their operations carefully to make sure ships are loaded and unloaded on time. At a terminal, it is common that some containers need to be transhipped between vessels. A missed connection requires finding alternative routes and can have a significant negative impact on delivery times and customer satisfaction. However, forcing a planned transshipment to happen under unfavorable circumstances can be very expensive if it affects other vessels calling the port, while allowing it to be missed and using alternative routes could be done at low cost. Therefore, terminal operators are frequently facing trade-offs that are challenging to arbitrate manually due to the scale of operations. In this context, the use of OR-based decision-support tools can be of great help. We present a mathematical model of a problem where the objective is at the same time to 1) find a berthing and quay crane allocation plan for the vessels calling a terminal over a planning horizon and 2) assign an alternative route to each container that misses a transshipment, at a minimum total cost. We call it the Berth Allocation and Quay Crane Assignment Problem with Missed Transshipment Recovery. Besides a MIP formulation, we present resolution methods for a set of instances derived from industrial cases and provide insights about the solutions

2 - A novel robust exact decomposition algorithm for berth and quay crane allocation and scheduling problem considering uncertainty in worker productivity

Kaoutar Chargui, Tarik Zouadi, Tarik Chargui

This study proposes a novel robust version of berth and quay crane allocation and scheduling problem integrated with a quay crane worker assignment problem. To align with on-field data, we consider in this version that the processing rates of the quay cranes workers is not deterministic, but subject to uncertainties. The uncertainty of this parameter is addressed using robust optimization, by considering an uncertainty set of scenarios. A novel two-stage mixed integer linear programming model is proposed to minimize the worst-case tardiness of vessels and find the worst-case scenario from the uncertainty set. The model is first tested using a commercial solver, but it could not be solved, even for small instances. Thus, as we noticed that the problem has a decomposable structure, we developed an exact decomposition algorithm that splits the model into a master problem and a set of subproblems to alleviate the complexity. We also strengthened the algorithm by introducing novel (re)formulation enhancement, valid inequalities and lower bounds. To assess the performance of the proposed algorithm, we conducted a series of computational experiments on a dataset of instances designed from a real-case database of a container terminal. Also, we performed a sensitivity analysis to evaluate the value of considering a robust version of the model compared to a non-robust version.

3 - Distributionally robust optimization for the berth allocation problem under uncertainty

Filipe Rodrigues, Agostinho Agra

There are several optimization problems occurring in port terminals, and the berth allocation problem (BAP) is amongst the most important ones. The BAP is highly affected by uncertainty due to many factors like weather conditions and mechanical failures. Therefore, it is crucial to take uncertainty into account when approaching BAPs. Here, we study the BAP under a distributionally robust optimization (DRO) approach. We assume that each vessel has an associated deadline to finish its operations, but delays can occur. Therefore, we aim to minimize the worst-case of the expected sum of delays of vessels with respect to a set of possible probability distributions of the handling times. The proposed model is solved by an exact algorithm enhanced with several improvement strategies that drastically reduce the associated running time. The DRO model depends on a risk-parameter that makes it possible to obtain solutions with different degrees of protection against the risk. Extensive computational results comparing DRO, stochastic programming, and robust optimization are also reported.

4 - A MILP formulation for Integrated Production Planning, Berth Allocation, and Quay Crane Scheduling Problem in tidal ports with multiple quays

Nizar El Hachemi, Ibtissam Guissou, Michel Fender, Tarik Aouam, Agnes Gorge

In this study, we address the integrated production planning, berth allocation, and quay crane scheduling problem. The problem is formulated as a Mixed-Integer Linear Programming (MILP) model with the objective of maximizing total revenue while considering demurrage costs. The computational results are derived from both real-life instances and generated instances associated with the OCP Safi complex; an industrial fertilizer site operated by the OCP Group. The results show that we achieve near-optimal solutions in less than one hour using the CPLEX MIP solver.

Models for Financial Data and Risk Management

Stream: OR in Banking, Finance and Insurance: New Tools for Risk Management
Invited session

Chair: [Alessandro Mazzocoli](#)

1 - Detecting patterns in financial data through time-frequency domain clustering

Francesca Fortuna

This talk introduces a strategy for detecting representative patterns in a time series of financial data. The proposal can be framed in Functional Data Analysis, where the time series is considered as a sample observed on a discrete time grid of an underlying continuous function. We are interested in studying the dynamics of this time series from the perspectives of temporal evolution and frequency content. To this end, we adopt a wavelet transformation of the raw time series to recover the underlying function. Wavelets provide a multi-resolution representation where the signal is represented as the sum of a coarse signal approximation and a set of multiscale detail coefficients providing information about the temporal data at different frequency levels. This allows highlighting trends and cycles in the time domain, also assessing variance at different frequency levels. Our contribution is the development of a clustering method for Functional Data, in which the time series, represented as a matrix of wavelet coefficients, is navigated to discover interesting patterns. We propose splitting the time domain into non-overlapping frames and clustering the data by a functional k-means. In this approach, each centroid is a representative pattern of time frames. The distance used to compare data is an optimally weighted Euclidean distance giving weights to frequency components. In this sense, we propose a new clustering objective function and an algorithm that allows optimizing it.

2 - Wavelet-Entropy Risk-Predictability Measure for financial time series

Alessandro Mazzocoli, Loretta Mastroeni

Data has emerged as one of humanity's most critical resources. Specifically, the endeavor to forecast future events using data has garnered widespread attention. However, heightened volatility, infrequent occurrences, and rare events hinder data predictability, consequently elevating risk levels. Consequently, the inability to accurately predict future events exacerbates uncertainty and variability within a given scenario, signaling a subsequent rise in risk. In this paper, we examine data predictability by introducing a novel metric based on entropy and the wavelet transform. Notably, we demonstrate that data exhibit less predictability than anticipated due to the aforementioned fluctuations and low-frequency events. Moreover, we employ our methodology on real-world data, particularly focusing on commodity time series. Consequently, with this new metric, we ascertain a notable degree of unpredictability in the price time series under scrutiny, attributable to heightened volatility and the impact of low-frequency events.

3 - Waveform Dictionary Matching Pursuit for Denoising Step Function Signals in Finance

Pierluigi Vellucci

In signal analysis, noise often obscures crucial patterns in processes of interest, particularly in economic contexts where factors like liquidity trades and agent errors contribute to data distortion. Addressing this challenge involves managing noise through mathematical approaches. One common scenario arises when denoising signals characterized by step functions with numerous discontinuities, prevalent in economic and financial time series. The violation of stationarity assumptions complicates noise removal, often mischaracterizing noisy points as signal discontinuities, leading to erroneous forecasting and inference.

This paper proposes a flexible denoising approach leveraging a sparse representation framework, particularly focusing on approximating step functions using rectangular functions. The method adopts the Weak-Orthogonal Greedy Algorithm (WOGA) or matching pursuit (MP) to iteratively remove noise from step function-derived signals. By selecting elementary functions from a highly redundant set, the algorithm constructs an approximate orthogonal basis expansion of the signal, effectively capturing its discontinuities.

The paper establishes theoretical foundations for the proposed method, demonstrating its efficacy in capturing discontinuities while simplifying calculations. Specifically, theorems elucidate optimal conditions for waveform dictionary selection, facilitating efficient denoising iterations.

4 - Corporate Sustainability Commitment and marker risk

Rita D'Ecclesia, Kevyn Stefanelli, Susanna Levantesi

The impact of Environmental Social and Governance (ESG) factors on the performance of financial stocks are still controversial in the literature. We aim to identify groups of companies according to their ESG temporal dynamics to evaluate whether their fluctuations impact the market risk factors. We assess a potential relationship between financial and non-financial risks within the Fama and French framework (Fama and French, 2015) according to the ESG score and its components. We discriminate companies that increase their ESG compliance using a hierarchical time-series clustering approach and computing the similarity between two-time series by Euclidean distance and Dynamic Time Warping (DTW). The latter is useful when the time series have different shifts and speeds. We compare four hierarchical methods with different linkage criteria (average, complete, Ward.D, Ward.D2). The optimal number of clusters is selected based on 4 cluster validity indices (Silhouette, Calinski-Harabasz, Clustering Order Preservation, and Dunn). The data utilized in this paper refer to the S&P500 and come from the Renitiv database. The CVIs indicate two clusters as the best choice. However, while the Euclidean distance with the average method is the best combination for the ESG score and its components E and S, the DTW distance with the Ward.D method is the best for the G score. Overall, we find different effects on the market risk, which depend on the ESG component

A vehicle starts its route from a depot and visits N unordered customers. New goods are delivered to the customers and expired goods are collected from them. The demands of the customers are stochastic with known distributions. The actual demands are revealed when the vehicle arrives at each customer's site. During its route, the vehicle may return to the depot in order to unload expired goods and to restock with new goods. The cost structure includes travel costs between customers and travel costs between each customer and the depot. After the first visit at each customer's site two decisions must be made. The first decision is to choose the next customer that the vehicle will visit. The second decision is to choose how the vehicle will go to the next customer. The problem is to find (i) the minimum total expected cost for servicing all customers and (ii) the optimal decisions that must be made after the first visit at each customer's site. A suitable stochastic dynamic programming algorithm is developed for the solution of the above problem.

2 - Solution Strategies for the Stochastic Dynamic Contagious Disease Testing Program

Emilio Jose Alarcon Ortega, David Wolfinger, Margaretha Gansterer, Karl Doerner

In this talk, we present a stochastic and dynamic variant of the Control Disease Testing Program (CDTP) that originated in the late COVID-19 global pandemic. The CDTS was proven to be a key strategy to contain and control the pandemic, where suspected cases required to remain isolated and be tested. These results must be available quickly for the CDTS to be effective. We address the stochastic and dynamic version of the problem remark: repetition of the first sentence, maybe this part can be deleted, where only some suspected cases are known in advance, and new suspected cases could appear randomly throughout the course of the day or planning horizon. When a new suspected case arrives, it must be decided whether to include the new test request in the current plan or reject it. The specimens of the accepted requests must be collected on the same day; either by assigning the case to a time slot in a test-center or by visiting the patient with a mobile test-team. On the other hand, rejected requests must be included in the plan for the next day. The aim of this problem is to decide how many mobile test-teams to use, how many test-centers to open and where, which suspected cases to visit with a mobile test-team and which to assign to a test-center, and design the vehicle routes for the mobile test-teams. To solve this problem, we propose a solution method based on value function approximation and compare the effectiveness of the algorithm with respect to benchmark solution approach

3 - PyVRP and ICD: Results From the EURO Meets NeurIPS 2022 Vehicle Routing Competition

Leon Lan, Niels Wouda, Wouter Kool, Jasper van Doorn, Arpan Rijal, Sandjai Bhulai

In this talk, we highlight our work that secured first and third place in the EURO Meets NeurIPS 2022 Vehicle Routing Competition on the static and dynamic track, respectively. First, we introduce PyVRP, an open-source and state-of-the-art VRP solver in Python that builds on Thibaut Vidal's hybrid genetic search algorithm. Through PyVRP, we hope to provide researchers and practitioners the means to build upon a state-of-the-art VRP solver easily and quickly without diving deep into the algorithmic details. Second, we present iterative conditional dispatch (ICD): a simple yet effective algorithm for dynamic vehicle routing problems with stochastic requests. ICD iteratively solves sample scenarios to classify requests to be dispatched, postponed, or undecided. The set of undecided requests shrinks in each iteration until a final dispatching decision is made in the last iteration. A significant strength of ICD is that it is conceptually simple and easy to implement. This simplicity does not harm performance: we show that ICD can nearly match the winning machine learning-based strategy of the EURO Meets NeurIPS 2022 Vehicle Routing Competition. PyVRP and ICD are forthcoming in the INFORMS Journal on Computing and Transportation Science, respectively.

1 - A Pick-Up and Delivery Vehicle Routing Problem With Stochastic Demands and Unordered Customers

Epaminondas Kyriakidis, Theodosios Dimitrakos, Andreas Papasalouros

In this presentation, we address the vehicle routing problem with time windows and synchronized visits with uncertain service and travel times. Specifically, a subset of the clients require simultaneous service by two vehicles, which is initiated only after the arrival of both vehicles and, consequently, enforces a waiting period for the vehicle that arrived earlier. To tackle this problem, we propose an optimization-simulation framework. Through an iterative process, a stochastic optimization model generates potential solutions which are then assessed through a simulation model. If the solution is found to lead to a bad average and/or worst-case performance, new scenarios suggested by the simulation are added to the stochastic optimization model. This iterative process continues until all performance criteria are satisfied. We validate our approach through experiments on benchmark instances from the literature.

1 - A Contextual Stochastic Optimization Perspective on Demand Prediction for Decision Making

Emma Frejinger

Decision makers are often faced with problems that are subject to uncertainty. Consider the problem of planning transport services for an upcoming season, determining optimal locations of new infrastructure, or establishing production plans and pricing strategies for a product. In this context, demand uncertainty is challenging to deal with, notably because it is decision-dependent. In this talk, we discuss data and modeling challenges associated with understanding and predicting demand. Focusing on the competitive facility location problem, we describe a methodology to deal with decision-dependent demand uncertainty without making strong distributional assumptions. We also provide a high-level overview of contextual stochastic optimization. Studied in the literature under a variety of names, contextual optimization refers to data-driven approaches to prescribe decisions by exploiting relevant side information. We position demand modeling for decision making in this context and outline future research directions on integrated learning and optimization.

1 - Learning optimal courier assignments in on-demand delivery platforms

Gökhan Ceyhan, Pol Arias

On-demand delivery platforms are characterised by uncertain demand with spatiotemporal patterns and short delivery time targets. Platform operators manage a courier fleet aiming to deliver the orders as quickly as possible and in a cost-efficient way. A core component of the platform is the courier assignment algorithm assigning incoming orders to couriers in real-time and determining a sequence of pickups and deliveries for each courier. Column generation is commonly used to solve these types of problems in practice: First, a set of feasible columns is generated via sequencing algorithms. Then, a set-partitioning problem is solved with the generated set of columns. As the size of the problem increases with the number of columns included in the problem, it is essential to include only the columns that are likely to be optimal in the problem. Our study aims to learn the optimal columns via machine learning utilising the characteristics of the problem instance and the feasible decision space. We then improve the efficiency and the solution quality of the algorithm by favouring the columns that are more likely to be part of the optimal solution. We conduct computational studies on a set of historical instances utilising the optimality predictions generated by the trained machine learning model and evaluate in terms of solution quality and run times.

2 - A decision support framework for automated reviewer assignment using nlp and optimization

Meltem Aksoy, Seda Yanik, Mehmet Fatih Amasyali

Addressing the inefficiency of traditional manual reviewer assignments in the peer-review process, this study introduces a decision support system that automates the assignment task. Utilizing information retrieval, natural language processing (NLP) and optimization techniques, it tackles the reviewer assignment problem through a structured, three-stage approach. Initially, it gathers diverse information from various sources to build a comprehensive database of proposals and reviewers. Then, it applies word embedding techniques to convert multilingual proposal and reviewer texts into vector representations, and it uses the cosine similarity metric to determine content similarity between each proposal-reviewer pair. Concurrently, it assesses reviewer competency by analyzing their past evaluation performance and areas of expertise through predefined knowledge rules. In the final stage, a multi-objective integer linear programming model assigns reviewers to proposals, optimizing proposal-reviewer similarity and reviewer competency while avoiding conflicts of interest. Furthermore, it explores a max-min approach to improve outcomes for the least-advantaged proposals. This model is enhanced by two additional models to ensure balanced reviewer workloads. The system's efficiency is tested with a real-world dataset from the project proposal evaluation process of a regional development agency. The results show that the proposed system significantly outperforms traditional methods.

3 - Harnessing the Power Trained Reinforcement Learning Agents in Job Shop Scheduling Problems

Constantin Waubert de Puiseau, Hasan Tercan, Tobias Meisen

The Job Shop Scheduling Problem (JSSP) has been extensively studied in operations research for decades, resulting in the development of various solution methods. Recently, deep reinforcement learning (DRL) has emerged as a promising approach to automatically learn generalized construction heuristics from simulations. Construction heuristics iteratively generate solution sequences in which operations are integrated into a schedule. The neural networks of DRL-agents predict the probabilities per operation, that integrating it next in sequence will lead to the shortest schedule. Often multiple solutions are sampled stochastically from the predictions of trained agents. However, due to the symmetry of the JSSP, many of these sequences result in the same makespan or even the same schedule. This motivates the use of more sophisticated search strategies that cover a wider range of solutions and utilize trained agents effectively. This study compares theoretical and practical aspects of integrating learned priors into depth-wise search strategies, such as stochastic sampling and Monte-Carlo tree search, aiming to find the shortest makespan in limited computational time. While predictions for sampling are most efficiently parallelized, other methods effectively prune the search tree to require fewer predictions in total. Our results with state-of-the-art DRL agents indicate that variations of stochastic sampling perform best, considering realistic time and hardware constraints.

4 - Decision-focused learning with machine learning proxies for energy storage system optimization in energy markets

Ruben Smets, Mathieu Tanneau, Jean-François Toubeau, Kenneth Bruninx, Pascal Van Hentenryck, Erik Delarue

In various sectors like energy, finance, and supply chain management, decision-makers optimize their decisions using forecast-informed optimization. In particular, energy market participants base their decisions on price forecasts. In this context, Decision-Focused Learning (DFL) has emerged, where the downstream decision problem is explicitly considered in the training procedure of the forecaster. This forecasting model is typically a neural network, which is trained using a gradient descent-based procedure. A pivotal challenge in DFL training is ensuring that the optimal decisions are differentiable with respect to the input parameters, being the price forecasts. A promising solution involves implicit differentiation of KKT conditions, albeit this significantly slows down training since it requires solving many optimization problems with every forward pass during training. We propose an innovative workaround using a Machine Learning (ML) proxy to replace

the optimization problem in the forward pass. This approach is applied to Energy Storage Systems (ESS) participating in day-ahead and real-time balancing markets. Applying duality theory to the ESS optimization program allows us to simplify the ML proxy model, limiting its output to the dual variable of the energy balance constraint. We observe similar out-of-sample profit performance as traditional DFL methods, while reducing training time by 70% to 95%, illustrating the improved scalability of the proposed method.

Topics in Mixed Integer Nonlinear Programming 1

Stream: MINLP

Invited session

Chair: Jan Kronqvist

Chair: Luca Mencarelli

1 - A combined Lagrange-Benders approach to Delay Constrained Routing

Antonio Frangioni, Laura Galli, Enrico Sorbera

Modern computer networks are required, on one hand, to support high bandwidth applications, on the other hand, to have stringent Quality of Service (QoS) guarantees. This is a relevant practical issue, since many applications over IP networks require QoS in terms of real-time guarantees, that is, controlled end-to-end delay. This implies that Internet Service Providers are required to negotiate delay bound within their Service Level Agreements, which in turn requires appropriate traffic engineering support. From a mathematical point of view, this problem, known as Delay Constrained Routing (DCR), can be formulated as a Mixed-Integer Nonlinear Program, where one needs to simultaneously compute paths and reserve resources along the paths of the network, since the maximum delay of a flow depends (in a non-linear way) on both. Even in the single-flow case, DCR is significantly more difficult than classical shortest path routing problems. Yet, DCR presents an interesting mixture of combinatorial and continuous structures and naturally lends itself to decomposition methods. We propose a combined Lagrange-Benders approach that provides both upper and lower bounds of very good quality in extremely short computing times.

2 - A dual decomposition approach for convex problems with linear complementarity constraints

Luca Mencarelli, Giandomenico Mastroeni

In this talk, we tackle general convex mathematical programs with a complementarity constraint. We introduce a novel decomposition method for this latter problem build on a sequence of convex parametrised sub-problems. Via Wolfe duality theory, we derive optimality conditions to improve the optimal value of the parametrised sub-problems and valid linear inequality cuts. Moreover, we present preliminary encouraging experimental results for quadratic convex problems with complementarity constraints and convex binary programs.

3 - On the Piecewise Convex Approximations of Two-Variables Functions

Claudia D'Ambrosio, Antonio Frangioni, Claudio Gentile

In the literature, different approaches have been proposed to approximate two-variable nonlinear functions. In particular, classic piecewise linear approximation, based on triangulation of the function domain is one of the most widely used in practice. We start from a different approach, originally proposed in Rovatti et al. (2014), that allows one to obtain piecewise linear approximation by dividing into rectangles the nonlinear function domain. Rovatti et al. studied formulations for modeling such an approximation, using a number of binary variables that is equal to $j + k$, where j (respectively, k) is the number of intervals in which the first (resp. second) variable is divided. Note that the classic formulations of piecewise linear approximations based on

triangulations need $2 \times j \times k$ binary variables instead. In this work, we consider the generalization of the work by Rovatti et al. (2014) to the piecewise convex approximation case. In particular, we explore the strengthening of mathematical formulations to model such approximations via perspective reformulations. Finally, we show their interest thanks to some preliminary computational results.

4 - Efficient and effective optimization methods for sparse generalized inverses

Jon Lee, Marcia Fampa, Gabriel Oliveira da Ponte, Luze Xu

The Moore-Penrose (M-P) pseudo-inverse has a prominent place in matrix theory and applications. It is well-known that the M-P pseudo-inverse is characterized by the four M-P properties. But not all of these properties are needed for the use of it in applications like least-squares fitting. In particular, when a matrix is not full rank, as is common in modern applications, there are much sparser (and even block structured, for explainability) generalized inverses than the M-P pseudo-inverse that solve the least-squares problem for arbitrary response vectors. Besides sparsity and structured sparsity, we are interested in low-rank and low-norm solutions, for further explainability and numerical stability. So, we attack the problem of generating such generalized inverses using optimization methods. Our techniques include: linear programming (LP), second-order cone programming (SOCP), local-search based approximation methods, the alternating direction method of multipliers (ADMM), and accelerations of these ideas via new structural results on generalized inverses.

Invited session

Chair: Gordon Dash

Chair: Nina Kajiji

Chair: Gerhard-Wilhelm Weber

1 - Characterisation of robustness measures for complex networks under attacks

Reetendra Singh, Shivshanker Singh Patel

In the globe, human and non-human systems are highly connected as complex networks. Complexity is understood as the property that is defined by the nature of interconnectedness, links and size of the network. As example, business and society are made of supply chain and societal community network. These networks are susceptible to attacks; we have considered two scenarios: (A) purposeful attack and (B) random attack. This study aims to investigate the robustness of complex networks during the attacks and how the complexity of networks changes under the attacks. And suggests algorithms and analytics to identify vulnerable complex networks. The application is shown on two different data sets for complex networks. The first is for the supply chain with materials flow and contractual relationships networks. The second is for community networks. Results and analysis show that some complex networks are less vulnerable to attacks, and some are more vulnerable. Further, the results show the characterisation of the robustness measure for different complex networks during attacks and the changes in the network property under the attacks.

2 - Evidential reasoning-based inference of early-stage information propagation source in large-scale social networks

Yuwang Chen, Tao Wen

The emergence of social media has transcended the constraints of time and space in communication, facilitating instant interaction among individuals. However, the influx of massive information has led to the widespread dissemination of fake news and deep fakes across online social networks. Identifying the source of fake news promptly and accurately has become a focal point of research. To mitigate the escalation of such situations at an early stage, only information from a limited number of observers can be utilized. Hence, this work first optimizes the deployment of observers in large-scale social networks, achieving maximized coverage and sufficient information collection. Moreover, each observer can provide only limited information, including the time of receiving information and their respective location. In this work, multi-source spatiotemporal data from pairs and a series of observers are integrated by the evidential reasoning algorithm, with weight coefficients determined by the structural characteristics of observers. Through simulation experiments conducted on real-world networks and information propagation paths extracted from Twitter, the proposed method accurately traces the propagation source, demonstrated by superior accuracy and error distance compared to typical algorithms. Such advancements can be further applied in other contexts, such as the management and intervention of infectious diseases within epidemic networks.

3 - Multi-armed bandits games

Kemal Gursoy

A sequential optimization model, the multi-armed bandit problem, is concerned with optimal allocation of resources between competing activities, in order to generate the most likely benefits.

In this work, following the objective of a multi-armed bandit problem, we consider a game theoretic model to approach to an ensemble of multi-armed bandits.

4 - Diagnostic advancements: machine learning in identifying nontuberculous mycobacteria (NTM) in non-cystic fibrosis bronchiectasis (NCFBr) population

Chen Hajaj

In the realm of pulmonary health, diagnosing Nontuberculous mycobacteria (NTM) infections presents a formidable challenge, particularly in patients with non-cystic fibrosis bronchiectasis (NCFBr). These infections are notoriously elusive, with their clinical presentations and radiological findings mirroring a plethora of other pulmonary conditions, thereby complicating accurate diagnosis. Our study embarked on an ambitious journey to harness the potential of machine learning in predicting NTM infections within this patient demographic. Through a comprehensive retrospective analysis of 771 NCFBr patients, our investigation illuminated the presence of NTM in 12.2% of cases, as confirmed by bronchoscopy cultures. Our findings advocate a paradigm shift towards incorporating machine learning as an integral component of the diagnostic toolkit for NTM infections in NCFBr patients. Delving into the intricacies of machine learning, we meticulously evaluated seven distinct models, with the Naive Bayes and Random Forest models emerging as frontrunners, boasting AUCs of 0.81 and 0.71, respectively. This comparative analysis not only underscored the viability of machine learning in the clinical prediction landscape but also highlighted the critical role of radiological and clinical parameters—most notably, patient age and the presence of GERD—in refining predictive accuracy.

Behavioural Studies in Health Care

Stream: Behavioural OR

Invited session

Chair: Monica Oliveira

1 - Collaboration and decision-making patterns between allied health- and primary care professionals using game theoretical models

Tijmen Geurts, Femke Bekius, Dorien Oostra, Marieke Perry

Allied health professionals possess expertise to improve primary care for frail older adults but structural interprofessional collaboration remains difficult. We aim to characterize person and group-level behavioral factors influencing collaboration and decision-making between care professionals. We conducted 24 semi-structured interviews with allied health- and other primary care professionals and asked about collaborative experiences between disciplines. We deductively coded the interviews with elements (actors, actions and outcomes) of three game theoretical models (Principal-Agent (PA) game, Volunteer's Dilemma (VD) and Battle of the Sexes (BS)) to characterize collaboration patterns. We found empirical situations of behavioral patterns representing characteristics of each model. Based on these patterns, we clustered situations on two axes, resulting in four categories. PA games differentiate between the principal using power or the agent's information to decide, and direct versus indirect collaboration between professionals. VD-games show waiting or volunteering behavior, central to patient care or professionals themselves. BS-games differ between collaborative- and conflict-inducing behavior, and resulting collective or individual actions. Our findings may help raise awareness of (un)desirable dynamics in primary care collaboration and decision-making. Furthermore, it provides starting points to change behavioral patterns and improve collaboration.

2 - Developing an Evaluation System for Health-Smart Homes for the Elderly Based on Dynamic Z-Number Fuzzy Delphi Method

Jian-hua Xia, Jhy Ping Jhang, Huang Sun-weng., Gwo-Hshiung Tzeng

Traditional smart homes emphasize the convenience brought by information technology, yet the elderly face certain challenges in accepting and mastering technological capabilities. Thus, understanding what constitutes an elderly-friendly health-smart home according to their expectations becomes a focal point in housing policies for ultra-aged societies. This study aims to construct an evaluation framework for health-smart homes based on exploring the perspectives of the elderly. Firstly, a semi-open format will be utilized to collect indicators of concern for the elderly. Secondly, dynamic Z-number will be employed to quantify the inconsistency and uncertainty in the decision-making process of the elderly. Finally, fuzzy Delphi method will be utilized to gather decision consensus. The research outcome will establish standards for evaluating elderly-friendly health-smart homes, contributing to the overall development of housing policies in ultra-aged societies.

3 - Promoting circular economy concerns in medical devices' procurement through structured collaborative processes

Francisco Viterbo, Ana Carvalho, Ana Vieira, Mónica Oliveira

Portuguese health spending has been rising, with the global health sector contributing 4.6% to worldwide greenhouse gas emissions. Single-Use Medical Devices (SUMD) are increasingly used in healthcare and their procurement is mostly price-based, with literature recognising the need to implement sustainable procurement practices but studies in the area being scarce. This study aims at identifying, with stakeholder engagement, which aspects related to the evaluation of SUMD should be considered to leverage a more circular healthcare system. A novel multimethodology, integrating Problem Structuring Methods within a Delphi to promote structured collaboration and address aspect interconnectedness, is proposed and tested in a case study with twenty Portuguese stakeholders. In Round 0, participants ideated new aspects to consider in evaluating medical devices to promote circular economy concerns. These aspects were organised into a cognitive map made available to participants in rounds 1 and 2, where participants stated their agreement level with each one and revised their views in light of the group's answers; and provided feedback about the Delphi. Twelve experts completed all rounds and results were validated through individual interviews with a core strategic group. Results suggest many

new value aspects for evaluating SUMD. The adopted multimethodology was effective in depicting interrelationships between value aspects and promoting stakeholder agreement.

Game Theoretic Market Equilibrium Modelling

Stream: Energy Markets

Invited session

Chair: *Mel Devine*

1 - Valuing the Electricity Produced Locally in Renewable Energy Communities through Noncooperative Resources Scheduling Games

Louise Sadoine, Zacharie De Greve, Thomas Brihaye

Renewable energy communities play a crucial role in the energy transition. Members own distributed energy resources and are stakeholders of their own energy supply. We propose two market designs for the optimal day-ahead scheduling of internal energy exchanges. The first one implements a collaborative demand-side management scheme inside a community where members objectives are coupled through grid tariffs, the second allows the valuation of excess generation in the community and on the retail market. Two grid tariff structures are tested, one academic and one which reflects the Belgian regulations in terms of grid tariffs. Individuals' bills are obtained through 4 cost allocation methods. Both designs are formulated as optimization problems and as noncooperative games. In the latter case, the existence and efficiency of the corresponding (generalized) Nash Equilibria are studied and algorithms for finding these are proposed. The models are tested on a use-case of 55 members and compared with a benchmark situation where members act individually. We compute the global and individual costs, inefficiencies of decentralized models compared to social optima, as well as technical indices. First, we show that there always exists an equilibrium that is a social optimum. Secondly, we show, analytically when possible, and empirically if not, that the community and the individuals' bills obtained with the centralized and decentralized approaches are equivalent.

2 - The interactions between demand- and supply-side investment decisions in an oligopolistic electricity market.

Mel Devine, Valentin Bertsch

To meet carbon reduction targets, there will need to be investment in wind energy, solar PV, and battery storage in electricity markets across the world. In this work, we consider what the optimal investment mix for these technologies will be from the perspective of both generating firms and consumers. We present a stochastic Mixed Complementarity Problem where several generating firms maximise their profits while various consumer groups minimise their costs. All players modelled make hourly operational decisions in addition to long-term investment decisions. The generating firms may exert market power. The uncertainty of wind and solar PV are the sources of the model's stochasticity. We apply the model to a case study of the Irish electricity system in 2030. We consider the optimal investment mix when market power is both present and absent from the market. We observe that the presence of market power increases electricity prices which leads to increased generating firms' profits and consumer costs. It also leads to increased investment in renewable technologies and battery storage, which leads to reduced carbon emissions. Furthermore, we consider the effect a Feed-in-Premium (FiP) has on renewable investment and observe a counter-intuitive result whereby the absence of a FiP leads to less investment in renewables from generation companies but, consequently, increased investment in renewables from consumers.

3 - Risk Measures in Stochastic Complementarity Models of Energy Markets

Dáire Byrne, Mel Devine

With the transition towards renewable energy sources, there is a growing need to capture uncertainty within energy market models, with firms facing stochasticity in terms of costs, demands, and generation capacity. With this heightened variability comes additional exposure to risk, leading firms to exhibit risk-averse decision-making. In order to account for this, risk measures can be appended to models. A number of such measures, particularly conditional value-at-risk, stochastic dominance constraints, and concave utility functions, have gained varying degrees of traction in energy market modelling literature. This study aims to investigate the consequences of these risk measures on the behaviour of price-making players acting competitively and seeking to maximise profits. It comprises a discussion of these risk measures and their relative merits. It further includes an analysis of the impact of incorporating risk measures into stochastic equilibrium models, both from an analytic and numerical perspective. Moreover, it discusses the circumstances under which these complementarity problems can be converted to an equivalent problems in convex optimisation, and the use of Arrow-Debreu securities to conceptually complete the market. This work aims to elucidate and illustrate the behaviour of these risk measures and their appropriate application to energy markets.

4 - A Multi-Commodity Partial Equilibrium Model of Imperfect Competition in Future Global Hydrogen Markets

Lukas Barner

Recent techno-economic studies have investigated procurement costs of hydrogen and related derivatives on various international trade routes. However, strategic behavior of exporters has rarely been considered in this context, despite similar behavior frequently observed in the fossil fuel world and market characteristics indicating some potential. This work introduces a novel techno-economic model of oligopolistic trade tailored around the value chain of potential future global hydrogen markets. It is formulated as a mixed complementarity problem with a convex reformulation, allowing to solve both competitive and oligopolistic equilibria much beyond the capabilities of traditional complementarity models. Illustrative results show, that assuming perfectly competitive price formation in early phases of future global hydrogen markets may lead to overly optimistic price projections, especially within Europe, Japan and South Korea. In extreme cases, hydrogen prices may increase to ~200 EUR /MWh by 2030, compared against a competitive baseline of ~150 EUR /MWh. In contrast, prices may decrease by ~25 EUR /MWh in exporting regions, such as Northern Africa or South-Eastern America.

Tuesday, 10:30-12:00 - Room: 11 (building: 116)

Surgery Scheduling and Operating Room Planning

Stream: OR in Health Services (ORAHS)

Invited session

Chair: *Theresia van Essen*

1 - Intra-day optimization of the surgical suite: allocating and sequencing surgical cases

Taha Huzeife Aktas, Alex Kuiper

Limited resources in healthcare give rise to efficient use of resources. As operating rooms (ORs) and associated resources are dominant factors in the hospital's operational cost, our aim is to improve surgery scheduling. Considering Leefink, G. & Hans, E.W. (2018) as our starting point - a large benchmark of surgery scheduling problems - our objective is to improve the scheduling by taking uncertainty about surgery durations into our approach. The motivation stems from the

observation that in the literature, most studies tend to focus solely on specific cases of the surgery scheduling problem or operate under deterministic assumptions contrary to the problem's nature. Note that the classical problem is twofold: first, one needs to decide which procedures are done on which OR, and second, in which order do the procedures need to be scheduled. We propose a mathematical formula that merges applied probability and mixed-integer programming to minimize overtime and idle time. We demonstrate how our solution approach can be adapted to specific cases and integrated with additional constraints. We show superior results compared to the ones that simply assumed deterministic service times, and we also contrast them to scheduling rules. This underpins the importance of taking variation into account. Furthermore, our experiments show that even with a limited degree of information about the uncertainty, the performance of the surgery schedule can be considerably improved.

2 - Advancing elective surgery scheduling considering operating theatre and non-operating theatre resources with time and demand uncertainties

Mona Koushan, Lincoln Wood

The anticipated surge in demand for elective surgical services highlights the urgency of optimising hospital resources, especially in publicly funded systems with limited budgets. Effective coordination of materials and resources under operating theatre (OT) capacity management is essential to meet the rising volume of elective surgeries. This study introduces a novel multi-stage care facility model, emphasising the significance of both OT and non-OT processes, aiming to balance financial constraints with community satisfaction. It explores enhancing OT scheduling using the theory of variation and uncertainty buffering, incorporating a time buffer into the surgical process. Furthermore, the study addresses uncertainties related to emergency arrivals and processing time, employing robust optimisation to ensure adequate capacity at each stage of the surgery process, thereby enhancing the model's relevance and realism. Solving this model, the study proposes meta-heuristic algorithms like Hybrid Nondominated Sorting Genetic Algorithm and hybrid Multi-Objective Firefly Optimisation algorithms with Hybrid Non-dominated Sorting Genetic Algorithm to efficiently address real-world scale scheduling problems. These meta-heuristics facilitate rapid adjustments in schedules in response to evolving circumstances, making them valuable tools for healthcare practice. This study enhances surgical service delivery and resource management in hospitals by advancing understanding of OT scheduling.

3 - Machine Learning of Chance Constraints for Scheduling Surgeries

Thomas Adams

We describe several methods for approximating chance constraints on the duration of surgeries assigned to a surgical session. We use historical data to create an empirical distribution of the session duration and employ SVMs and Probit regression to learn the probability that a session runs overtime, given the surgeries scheduled in it. These models are chosen as linear constraints can easily be formed from the results. Through numerical experiments, we demonstrate the accuracy of these models to act as binary classifiers, and their effectiveness as approximations to chance constraints. We compare them to a distributionally robust approach to approximating the chance constraints, and show that they result in similar, in many cases exactly the same, schedules but require much less time to solve the optimisation problem.

4 - Dealing with uncertainty in surgery duration

Theresia van Essen

Operating rooms are one of the most expensive resources of a hospital, which makes it important to use them as efficiently as possible. This involves maximizing utilization, but also minimizing the probability of overtime, which are two conflicting objectives. The problem of scheduling surgeries is usually modelled as an integer linear program (ILP), where maximizing utilization is considered as objective, while restricting the probability of overtime. The constraint used to restrict the probability of overtime includes the lognormally distributed surgery duration, which typically leads to a nonlinear constraint where the total surgery duration in one operating room is a stochastic variable. In the literature, various ways to deal with this nonlinearity are

considered: 1) only use the expected surgery duration and limit the total surgery duration, 2) model the uncertain surgery duration using a normal distribution and linearize the resulting constraint using a piecewise linear function, 3) model the uncertain surgery duration using a discrete probability distribution resulting in a linear constraint, and 4) model the uncertain surgery duration using the lognormal distribution and use column generation and simulation to solve the resulting model. We implemented and compared all mentioned methods on both solution quality and computation time. To determine the solution quality, we tested the resulting schedules using simulation.

Tuesday, 10:30-12:00 - Room: 12 (building: 116)

Behavioral OR general papers

Stream: Behavioural OR

Invited session

Chair: *L. Alberto Franco*

Chair: *Raimo P. Hämmäläinen*

1 - The role of theory in behavioral operations research

Michael Leyer, Aysegül Engin, Marta Lopes, Anita Onay, Lisa Scholten

Behavioral OR (BOR) is positioned between hard and soft OR and provides analyses of human behavior in decision making so that it can be modeled with OR tools. Although behavioral analyses have always been integral to OR, scientific rigor and especially theory-based analyses are required to strengthen the research field. From our perspective, BOR bridges distinguishable world views and describes how behavioral dimensions influence OR problems and solutions. The goal of this research is to clarify the areas where BOR research can provide insights to increase scientific rigor. We provide a theoretical foundation that improves the positioning of BOR using the concept of "wickedness". It structures typical OR problems according to their degree of wickedness that increases with the complexity of problems and the difficulty regarding stakeholders and institutions. Decision making in very wicked settings is grounded in belief functions that can differ between individuals due to insufficient knowledge or deviating goals of individuals involved. By identifying relevant assumptions from theories, this research aims to clarify beliefs so that they can be calculated in models. This analysis serves as a foundation to derive relevant types of theories that can be used from other fields (mainly from related fields e.g. psychology). Moreover, novel specific OR theories are intended to be developed based on the adopted ones. Our work contributes to the understanding of BOR as a discipline.

2 - Facilitated modelling revisited: A conceptual development

L. Alberto Franco, Etienne Rouwette

Facilitated modelling (FM) is an intervention process by which operational research models are jointly developed with a group tasked with addressing a situation that requires attention and action. The process requires operational researchers to act both as analysts and facilitators, and is designed to help the group make progress with regards to the situation of interest. The aim of this paper is to propose a conceptual framework that can act as a guide for the study of FM processes and outputs, and the design and use of FM interventions. The framework is comprised of three elements: groups as motivated information processors, models as boundary objects, and facilitation as intervention. Each of these elements is discussed with working propositions formulated for core FM processes and outputs. Implications of the framework for the study and practice of FM are discussed, and directions for future research proposed.

3 - Incorporating Human Factors and Human Behavior into Research on Workload Control

Anita Onay

To enhance production planning through a proactive lead time management approach, the Workload Control (WLC) concept encompasses a robust framework with multiple hierarchical planning layers. Despite the considerable body of research on Workload Control (WLC) and hierarchical production planning, there exists a noticeable gap in incorporating behavioral operational research (BOR) into these domains. This present study explores the relationship between instructions from the upper planning layer and the human response behavior of a lower hierarchical level within a comprehensive WLC system. The article particularly emphasizes that the arousal level, a human factor, influences the response behavior of shop floor operators. Through laboratory experiments with a real effort task and mediation analysis, this research reveals that tense arousal significantly impacts operators' response behavior in terms of productivity within a WLC environment with hierarchical planning layers. This outcome contradicts the assumption of the standard hierarchical model of rational behavior at the base level. Furthermore, the study contributed to the theory underpinning the WLC concept and its implementation issues with regard to a human-operated shop floor.

4 - Keeping your enemies closer? The effect of the fear of replacement by AI on AI-augmented decision-making

S. Iman Moosavi, Jan C. Fransoo, Prisca Brosi

In addition to various behavioral biases and contextual factors affecting AI-augmented decision-making, emotions play an important role in such tasks. Across different emotions, the fear of being replaced by AI systems is one of the most reported ones among those who are working with AI. Our study explores how the fear of being replaced by an AI-algorithm for operations decision-making affects individuals' reliance on AI suggestions and subsequent decision-making performance. Using an online experiment, we manipulate this emotion by varying the likelihood of the AI to replace participants in a demand-forecasting task. Participants are provided with additional information compared to the AI, mirroring real-life scenario of private information, and informed that they may lose their job and the opportunity for bonuses in additional tasks if they fail to improve on the algorithm's suggestion. Our pre-test's results suggest a marginally significant negative effect of the fear on the adoption of AI recommendation through decision-making process. However, there is no significant effect observed on decision-making performance.

OR in Forestry II

Stream: OR in Agriculture and Forestry

Invited session

Chair: *Lidija Zadnik Stirn*

1 - Enhancing Wildfire Management: A Comprehensive Approach Integrating System Dynamics and Remote Sensing Technologies

Müjgan Bilge Eriş, Fatih Duygun Demirel, Eylül Damla Gönül Sezer

Wildfires pose significant threats to human life, ecological balance, and the economy. The unpredictable and highly dynamic nature of wildfires emphasizes the need for analyzing wildfire management using non-linear methods. This study explores the causal relationships among the physical nature of fires, resource management, and the costs associated with prevention and suppression under various wildfire management policies via system dynamics approach. Our study extends previous works by incorporating remote sensing technologies

in the prevention stages of wildfires. The utilization of such technologies play a significant role in preventing the escalation of potential fires and ensuring the effective use of operational resources. Additionally, calculating the probabilities of errors through Failure Mode and Effect Analysis for potential errors in wildfire management further enrich the system dynamics model. The insights from the model will be provided for policy makers.

2 - Horizontal collaboration in forestry: game theory models and algorithms for trading demands

Gautier STauffer, Mourad Baiou, Gianpaolo Oriolo

In this paper, we introduce a new cooperative game theory model that we call production-distribution game to address a major open problem for operations research in forestry, raised by R"onnqvist et al. in 2015, namely, that of modelling and proposing efficient sharing principles for practical collaboration in transportation in this sector. The originality of our model lies in the fact that the value/strength of a player does not only depend on the individual cost or benefit of the objects she owns but also depends on her market shares (customers demand). We show however that the production-distribution game is an interesting special case of a market game introduced by Shapley and Shubik in 1969. As such it exhibits the nice property of having a non-empty core. We then prove that we can compute both the nucleolus and the Shapley value efficiently, in a nontrivial and interesting special case. We in particular provide two different algorithms to compute the nucleolus: a simple separation algorithm and a fast primal-dual algorithm. Our results can be used to tackle more general versions of the problem and we believe that our contribution paves the way towards solving the challenging open problem herein.

3 - Resilience of the long-term balance of ecosystem services in the landscape through integration of DEA, fuzzy AHP and DP: a case study in Slovenia

Lidija Zadnik Stirn, Špela Pezdevšek Malovrh, Vasja Leban

Landscape planning is not only about material production, but also about the provision of other services. The conservation and enhancement of landscapes to ensure ecosystem services (ES) for the benefit of society is an important issue in the field of OR. The aim of this study was to gain experience on how a decision support system based on MCDA can be used in practice for long-term landscape management. We present a planning tool that integrates DEA, Fuzzy AHP and DP. As a first step, it was crucial to know the current state of the landscapes. To this end, we used DEA to assess the operational efficiency of landscapes depending on a specific region (landscape unit), considering land use, land cover and ecosystem condition. Knowing that the provision of EFP is site-specific and dynamic due to changing natural conditions and influences as well as various other socio-economic and political factors, decision-makers define alternative management programs/scenarios for each unit under consideration. In the second step, the management criteria were selected and evaluated by the stakeholders. The Fuzzy AHP was chosen as the preferred weighting method for comparing the programs for each unit. Once all the alternatives, criteria and weightings are defined for each alternative per unit, the next step is to create a DP network for each unit to forecast the evolution of the unit to the target state, which depends on the ES supply/demand ratio in the unit.

Leroy White

The intersection of artificial intelligence and problem structuring presents new challenges and opportunities. The paper delves into leveraging AI problem structuring via data gathering, pruning, and strategy dialoguing, emphasizing the importance of moving from treating AI as a search tool to fostering meaningful dialogue. Experiments with generative AI based on large language models in strategy creation reveal valuable insights for ideation and evaluation.

2 - AI-enhanced spaces for problem structuring: better understanding, stakeholder engagement, and decision support?

Katharina Burger

This talk will delve into the opportunities and challenges of AI for problem-structuring that takes place in immersive virtual environments (IVEs). With the help of AI-powered technology, virtual reality (VR), is rapidly transforming how spaces for participatory problem structuring can be designed and experienced. For instance, AI is credited with making IVEs more realistic, interactive and adaptable, with 3D models that may aid in knowledge sharing and development. By allowing us to create immersive and interactive digital environments, participants are enabled to explore and refine their ideas in new and exciting ways. However, the use of virtual environments can alter the dynamics of interpersonal communication and collaboration. Moreover, while AI may enhance the usability of IVEs, questions remain about how interaction in IVEs generates specific impacts on knowledge production in such settings. In this talk, we will consider how problem structuring may evolve with the integration of AI-generated resources in and for interaction in IVEs while also considering some of the challenges involved relating to understanding, stakeholder engagement and decision support.

3 - Exploring Participatory Approaches: Integrating AI with Collective Intelligence in the Archivio Atena project

Sabrina Sacco, Piero Zizzania, Giuliano Poli, Maria Cerreta

In recent years, AI has witnessed a shift towards the inclusion of participatory approaches. This transition highlights the need of integrating AI with various methodologies, e.g. citizen science, crowdsourcing or digital democracy platforms. However, adopting a participatory approach means engaging communities and activating their Collective Intelligence (CI) across all stages of the AI system. Grounded in Activity Theory, this research aims to explore the potential of AI in gaining CI, facilitating the elicitation of collective values within communities and nurturing awareness and trust in AI tools. The research focuses on the Archivio Atena project, a culture-led initiative in Atena Lucana, in the South of Italy. Using image data collected during the project activities, the study encourages the community to participate in a collective supervised learning process for the AI, by tagging them with value-based labels. This iterative process enables participants to recognize collective value patterns, supporting data clustering and furnishing an evaluation tool for impact metrics within the future projects. The integration of AI with participatory methodologies offers a promising approach to address subjective and collective issues, beyond quantitative and objective realms. By leveraging AI in the context of PSMs, this research outlines both the limitations and potentials of AI in facilitating the promotion of CI and defining useful criteria for impact evaluation processes.

Appointment planning

Stream: OR in Health Services (ORAHs)
Invited session

Chair: Alex Kuiper

1 - A Column Generation-Based Exact Algorithm for Multiple Appointment Patient Scheduling

Mohammad Reihaneh, Sina Ansari, Farbod Farhadi

Scheduling patient appointments at a hemodialysis center introduces a unique scenario. In contrast to other healthcare appointment scheduling challenges, patients undergo a series of dialysis treatment appointments rather than a single one. In this study, we formulate the multiple-appointment system as a set-partitioning problem and solve it using a Branch and Price (BP) algorithm. The pricing subproblem proves to be challenging for the dynamic programming algorithm. Hence, we further decompose the pricing sub-problem and propose a column generation-based algorithm for solving the subproblem.

2 - Mathematical Programming for Scheduling Telemedicine Appointments

Charlotte Marshall, Daniel Gartner, Geraint Palmer, Paul Harper, Alka Ahuja, Gemma Johns

With telemedicine coming to the forefront during the COVID-19 pandemic, flexibility in terms of modes of care delivery has emerged. We are working with a partner within NHS Wales, TEC Cymru, who worked to rapidly implement video consultations within Wales during the pandemic and continue to promote the use of telemedicine in Wales. In this paper, we consider the scheduling of patients' appointments via three different modes of delivery: traditional face-to-face, video conferencing platforms, and telephone. The solution of the model not only has an impact on satisfying patient and clinician preferences, but also could potentially reduce travel for patients and staff. We model the problem as a multi-mode resource constrained project scheduling problem, with the aim of maximising patient and clinician preferences for delivery method. Two model formulations are presented to solve this problem. The first assigns appointments to timeslots while the second formulation assigns an ordering of appointments. We compare these two models, evaluating which is more useful in different scenarios.

3 - Rationing by Waiting Time for Outpatient Clinical Appointment Workflows via Novel Patient Access Workflows

Esma Gel, Derya Kilinc, Mustafa Sir, Kalyan Pasupathy

Increasing demand for healthcare has necessitated the need to ration care resources by prioritization. While such prioritization is effectively implemented in many settings, their use in appointment workflows have been impossible since appointments are provided on a first-come-first-serve basis. We present a novel approach to enable rationing by waiting time in outpatient settings offering clinical appointments. Under the Time Windows Access Protocol (TWAP), scheduling agents are provided a distinct contiguous portion of the booking horizon to search for an available appointment upon an appointment request at from a priority class. Patients with requests from high priority classes (i.e., urgent, complex, high match with provider services) are uniformly incentivized to book and attend appointments with low wait offers, while sufficient dilution of requests from lower priority classes are induced with higher (but still, medically safe) levels of wait. We present a computationally efficient methodology to determine the optimal time windows for given delay-dependent appointment realization probabilities that reflect patients' delay tolerance (i.e., sensitivity to wait). We demonstrate the potential use and effectiveness of TWAP for new patient appointment requests under different rationing schemes (i.e., the desired patient mix) using simulations as well as real-life transactional data from a leading academic medical center.

4 - Convexity in Transient Queues with Appointment-driven Arrivals and Implications on Optimal Appointment Scheduling

Alex Kuiper, Christos Zacharias

The inter-day (which day?) and intra-day (when?) appointment scheduling problems are often studied in isolation, whereas in reality, they are intertwined. If the waiting list becomes too large (small), one would want to extend (reduce) the appointment book, but such decisions directly impact the optimality of the schedule. Using a continuous intra-day scheduling paradigm, these problems are connected in a

dynamic environment. Extending convexity properties of the appointment scheduling problem renders the corresponding dynamic program amenable to building upon recent advances in literature.

Since the optimal solution is not tractable, two intra-day scheduling paradigms are introduced: a theoretical approach (based on re-optimization) and a heuristic, which is based on schedules that exhibit so-called sequential refinability. Together, they bound the optimal policy for the dynamic inter/intra-scheduling problem. At the same time, their small difference underscores the potential of using this heuristic in healthcare practice.

■ TB-16

Tuesday, 10:30-12:00 - Room: 19 (building: 116)

Ranking in sports

Stream: OR in Sports

Invited session

Chair: Balázs R. Sziklai

1 - Alternative UEFA country rankings based on pairwise comparisons

Dora Greta Petroczy, Laszlo Csato

UEFA country coefficients quantify the performance of UEFA associations' football clubs in international club competitions. They are based on the results achieved over the previous five years, with points awarded for match results and bonus points allocated for reaching different tournament stages. The points earned by all clubs from each country are divided by the number of participating clubs to calculate the coefficient. The ranking of UEFA associations by country coefficients is used to determine the number of clubs from the association that can participate in UEFA club coefficients, as well as the qualifying stage where they enter. Furthermore, two UEFA Champions League slots are provided for the two best associations in the previous year from the 2024/25 season. Therefore, it is crucial to obtain a fair ranking of European football leagues. For this purpose, we propose new methods based on pairwise comparisons that—in contrast to the current UEFA country coefficients—account for the strengths of opponents, and calculate alternative rankings based on matches played in the UEFA Champions League, UEFA Europa League, and UEFA Europa Conference League over the last 10 years. They will be compared to the official UEFA ranking, and the number of upsets (matches where the favourite team loses) will also be determined.

2 - FIVB ranking: a misstep in the right direction

Leszek Szczecinski, Salma Tenni, Daniel Gomes de Pinho Zanco

In 2019, Fédération Internationale de Volleyball (FIVB) introduced a new "power" ranking, which relies on the probabilistic model relating the teams' strengths to the obtained outcomes. While there are many rankings which already use such models, the FIVB ranking is the first official one which uses the explicit probabilistic model in multilevel games (that is, games with more than three results).

In this work, we explain/assess the model and the on-line ranking used by the FIVB, placing it in a general statistical framework. In particular, we describe the ordinal model used in the ranking, show why it cannot be used directly for on-line ranking, and explain the approximations adopted by the FIVB. We introduce analytical perspective which explain why the approximations are suboptimal and propose an alternative formulation which significantly simplifies the ranking. Our analysis is backed up by the numerical optimization, where we use the official FIVB games to fit and to optimize the models we consider.

We conclude that, while the use of the explicit probabilistic model for multilevel ordinal data is an interesting and refreshing change in the world of rankings, and should be a preferred ranking strategy, the resulting algorithm is too complex and suboptimal. We thus formulate a

number of recommendations, which vary in the amount of required changes and the performance/complexity trade-offs of the resulting rankings.

3 - Comparison of Football Leagues Using the Sum of Ranking Differences

Balázs R. Sziklai

The aim of the study is to demonstrate a new non-parametric statistical procedure, the Sum of Ranking Differences (SRD), through an example taken from sports. The method was introduced by Héberger (2010) and is becoming increasingly popular in various fields of applied sciences. With this procedure, solutions or methods can be compared through a reference. In our study, we analyze the similarities and differences in the style of play of four major European football leagues (La Liga, Bundesliga, Premier League, and Serie A). First, we characterize the leagues based on the teams' statistical attributes featured in the games. We assess the importance of game elements such as goals scored and conceded, ball possession, successful passes, etc., by examining how closely teams are ranked by each element in comparison to their final standings on the scoreboard. Essentially, this is an SRD calculation where the teams' final scores in the league serve as the reference. Aggregating the results for the leagues, we obtain a data table that can be subjected to yet another SRD analysis. By setting any league as a reference, we can measure how much the playing style of a particular league differs from the others.

Optimization of sustainable urban mobility II

Stream: Sustainable Cities

Invited session

Chair: [Virginia Pelleray](#)

1 - Guiding Local Authorities in Parcel Locker Adoption: A Case Study in Norway

Cosku Can Orhan, Stein W. Wallace

Urban population growth and the expansion of e-commerce have driven up the volume of deliveries, the need for faster shipping services, and a greater occurrence of delivery failures in cities. Consequently, there has been a noticeable increase in the number of trips made within urban areas to meet these demands, which intensifies the burden of freight transport. Driven by these considerations, we collaborate with local authorities in Bergen, Norway to analyse the impacts of freight transport on city liveability. In this work, we analyse the adoption of parcel lockers to provide authorities with insights on how the city could benefit from them as a sustainable delivery solution. By adopting clustering and vehicle routing models of freight carriers at a strategic level, we offer guidance to authorities on essential factors for improving city liveability through the utilization of parcel lockers. In this regard, we use data on the road network and population from local authorities, as well as the distribution data from a major carrier in Norway.

2 - Optimization of electric mobility investments in Kathmandu

Eric Vong, David Ruehmkorf, Dario Fiorica, George Panagakos, Michael Bruhn Barfod

The EU-funded SOLUTIONSplus project aims at promoting e-mobility in 9 cities around the world, including Kathmandu, Nepal. This paper develops a systematic approach for selecting the fleet of electric vehicles (among 8 different types including buses, shuttle vans, 3-wheelers, trucks, and waste collectors) that maximizes societal benefit within a specific budget. It introduces a framework combining Multi-Criteria Decision Making (MCDM) and optimization techniques. The MCDM aspect employs over twenty key performance indicators to assess the impact of various alternatives against specific

attributes that include financial viability, alignment with institutional framework, effects on climate change and environment, effects on society and the wider economy. A set of weights defines the values and priorities of the local stakeholders. As this problem is non-linear and the objective function is discontinuous, a metaheuristic is needed to find a good solution. It appears that the Evolutionary Algorithm produces good solutions at reasonable computational times. The proposed framework can identify an optimal solution configuration for problems with discontinuous objective functions and predefined preferences. In practical terms, this research not only advances the field of urban mobility but also offers a scalable model for other cities facing similar challenges.

3 - A Multi-Objective Optimization Approach for Electric Bus Fleet Conversion on the Istanbul Metrobus Line

Zahide Özden Ceylan Güngör, Sule Itir Satoglu

Transportation causes roughly 25% of global greenhouse gas emissions due to its reliance on fossil fuels (European Commission, 2011). In Turkey, road transport alone emits a staggering 93% of the sector (DEK, 2017). To combat this, electrifying public buses offers a promising solution for sustainable cities. Electric buses boast zero tailpipe emissions, significantly improving air quality (Hensher et al., 2022). They outperform diesel buses, which emit 1.35 kg of CO₂ per mile, highlighting their potential to reduce emissions.

This study explores the optimal electric bus fleet conversion planning problem (EBFT problem) aligned with the Paris Agreement's emission reduction goals. We propose a linear programming model for EBFT, considering direct/external costs alongside salvage value. The model optimizes for both economic (minimizing total fleet conversion cost) and environmental (minimizing total emissions) objectives. We incorporate four scenarios representing different electrification levels.

A case study using Istanbul's Metrobus data demonstrates a scenario-dependent optimal conversion plan. For Istanbul, gradual conversion achieves a 21% emissions reduction by 2030. This study employs a comprehensive optimization approach, considering multiple objectives, timeframes, and vehicle ages.

Tuesday, 10:30-12:00 - Room: 44 (building: 116)

The role of storage in energy problems

Stream: OR in Energy

Invited session

Chair: [Ann van Ackere](#)

1 - Big hydro, two islands, one goal: Exploring New Zealand's path to Net-Zero with Green Hydrogen integration

Rafaella Canessa, Jannik Haas, Rebecca Peer, Manuel Wetzel, Hans Christian Gils

Green hydrogen can play a crucial role in the energy transition but this role remains largely unquantified. This work presents the adaptation of REMix, an energy capacity expansion optimisation tool, for New Zealand (REMIX-NZ). With this, optimal pathways for achieving net-zero goals across energy sectors are evaluated. Unlike previous applications, REMIX-NZ considers New Zealand's unique characteristics, including: • High share of hydropower: The model leverages existing variable hydropower resources as the backbone while integrating additional renewables like wind and solar PV. • Medium-sized islanded system: This allows for detailed analysis of optimal energy import and export strategies, particularly for green hydrogen and its derivatives. We focus on the role and impact of green hydrogen, investigating its potential to decarbonise challenging sectors. This results in a large optimisation problem involving thousands of investments and millions of operation decision variables. The results illustrate the trade-offs and synergies between domestic energy needs and potential hydrogen exports, providing valuable insights for policymakers and stakeholders.

2 - Multi-Objective Energy-Aware Scheduling: A Memetic Two-Phase Evolutionary Approach incorporating Real-Time Energy Market, on-site Generation, and Storage Systems

Sascha C Burmeister, Daniela Guericke, Guido Schryen

Dynamic energy tariffs and on-site energy generation offer manufacturers new opportunities to optimize their energy consumption. In addition to conventional goals such as minimizing makespan, manufacturers can focus on minimizing energy costs or emissions. However, scheduling processes in the face of uncertain future energy prices and emissions is a major challenge. Energy storage systems (ESS) can compensate for differences between predicted and actual energy costs and emissions. To make an investment decision for ESS, decision makers need to assess their impact on energy costs and emissions, as well as their return on investment. In the literature, the Green Flexible Job Shop Scheduling Problem (FJSP) is concerned with resource and environmental aspects in addition to economic objectives. However, existing approaches neglect the combination of a multi-criteria objective with an uncertain dynamic energy mix and the use of ESS. We propose a two-phase approach based on a memetic NSGA-III and mathematical programming with the goal of minimizing a schedule's makespan, energy costs, and emissions, incorporating dynamic energy prices and emissions, on-site generation, and ESS. We evaluate the approach using FJSP benchmark instances from literature as part of a rolling horizon approach with real energy market data. We investigate the impact of ESS by presenting estimated Pareto fronts, showing potential savings in energy cost and carbon emissions.

3 - Security of supply in the transition to economically viable large-scale electricity storage

Ann van Ackere, Erik Larsen

While electricity storage is pivotal in the move away from fossil fuel-based generation to renewables, its roll-out might have undesirable side-effects. We develop a system dynamics simulation model to investigate the impact of introducing large-scale, economically viable storage, on security of supply during this transition period. As efficient storage options partly mitigate the intermittent nature of renewables such as wind and photovoltaics, their capacity factor will go up, resulting in an increased derated capacity margin, and thus a reduced need for future investments. However, the speed of the technological evolution that will enable large-scale viable storage, and the implementation rate, are hard to predict. Incorrect anticipation of future capacity factors could lead to a complicated transition period. If investors are over-optimistic regarding the speed of this evolution, they are likely to overestimate the efficiency of existing renewable generation and be reluctant to invest, leading to capacity adequacy problems and a risk of shortages, if not blackouts. On the contrary, underestimating the speed of this evolution would lead to costly over-capacity. The model allows us to investigate different scenarios based on investors' anticipations, initial share of renewables, etc. We observe capacity shortages in some scenarios, while others indeed generate significant excess capacity. Furthermore, we argue how the regulator might mitigate some of these issues.

4 - Stochastic multiobjective optimization for hybrid distributed generation with battery storage systems

Paulo Rotella Junior, Aglaucibelly Barbosa, Luiz Celio Souza Rocha, Arthur Leandro Guerra Pires, Karel Janda

Hybrid energy projects are attracting global interest due to the essential search for sustainable development, the alternative to oil price volatility, and the economic and environmental advantages of renewable energy sources. To contribute to filling the gap in the existing literature, which lacks an analysis considering the randomness of variables in a multiobjective optimization model, this study proposes a stochastic model for assessing the economic feasibility of a hybrid energy system comprising wind energy, photovoltaic generation, and battery energy storage. The model incorporates risks and uncertainties inherent in the critical variables associated with such investments. The multi-objective optimization employs the Design of Experiments with Response Surface Methodology and utilizes the Desirability function to

optimize the process. As a result, to maximize the average and minimize the standard deviation of the Net Present Value, an optimal configuration was obtained, represented by the combination of a system with 92% wind energy, 230 kWh/month of demand, use of a lithium-ion battery in a total scenario. Given the specific parameters and assumptions applied in this study, it is concluded that there is economic feasibility of wind photovoltaic projects with energy storage in batteries in regions with highly favorable wind regimes.

Demand Forecasting in Humanitarian Operations

Stream: OR in Humanitarian Operations (HOpe)

Invited session

Chair: [Emilia Grass](#)

1 - The Value of Demand Prediction for Improved Food Security

Alborz Hassanzadeh, Valérie Bélanger, Marie-Ève Rancourt, Fezay Sahinyazan

Hunger and famine pose great risks to global health and are the second in the UN's seventeen sustainable development goals to be achieved by 2030; however, they prove to be quite challenging to eradicate or alleviate. To mitigate their devastating impact, each year, aid agencies deliver tons of food commodities to populations in need. However, the delivery of food commodities is often expensive, and because of the complex intertwining factors shaping food security, it is very difficult to definitively predict future outcomes and demand for food aid. Without a timely identification of vulnerable populations, food aid often fails to arrive in the right place at the right time. We develop a stochastic optimization framework to assess the value of information: our analytical results quantify the advantages of incorporating food insecurity predictions in decision-making. Such predictions facilitate informed prepositioning decisions. Since acquiring relevant data might require heavy investments, we also analyze the delicate balance between allocating the limited available budget to the prepositioning of food commodities and investing in the acquisition of accurate data.

2 - A Machine Learning Approach to deal with Ambiguity in the Humanitarian Decision Making

Emilia Grass, Janosch Ortman, Burcu Balçık, Walter Rei

One of the major challenges for humanitarian organizations when planning relief efforts is dealing with the inherent ambiguity and uncertainty in disaster situations. The available information that comes from different sources in post-disaster settings may involve inconsistencies, which can severely hamper effective humanitarian decision making. In this talk, we present a new methodological framework based on graph clustering and stochastic optimization to support humanitarian decision makers in analyzing the implications of divergent estimates from multiple data sources on final decisions and efficiently integrating these estimates into decision making. We illustrate the proposed approach on a case study that focuses on locating shelters to serve internally displaced people in a conflict setting, specifically, the Syrian civil war. We use the needs assessment information published by different reliable sources to estimate the shelter needs in Idleb, Syria. The analysis of data has revealed a high degree of ambiguity due to inconsistent estimates. We apply the proposed methodology to integrate the ambiguous and divergent estimates into the decision making for determining shelter locations. The results highlight that our methodology leads to higher satisfaction of demand for shelters than other approaches. Moreover, we show that our solution integrates information coming from both sources more efficiently thereby hedging against the ambiguity more effectively.

3 - An efficient 2-competitive online algorithm for kit update at MSF Logistique

Mickael Gaury, Boris Detienne, Gautier STauffer

This paper explores strategic optimization in updating essential medical kits crucial for humanitarian emergencies. Recognizing the perishable nature of medical components, the study emphasizes the need for regular updates involving complex recovery, substitution and disposal processes with the associated costs. The goal is to minimize costs over an unpredictable time horizon. The introduction of the kit-update problem considers both deterministic and adversarial scenarios. Key performance indicators (KPIs), including updating time and destruction costs, are integrated into a comprehensive economic measure, emphasizing a strategic and cost-effective approach. The paper proposes an innovative online algorithm utilizing available information at each time period, demonstrating its 2-competitiveness. Comparative analyses include a stochastic multi-stage approach and four other algorithms representing former and current MSF policies, a greedy improvement of the MSF policy, and the perfect information approach. Analytics results on various instances show that the online algorithm is competitive in terms of cost with the stochastic formulation, with differences primarily in computation time. This research contributes to a nuanced understanding of the kit-update problem, providing a practical and efficient online algorithmic solution within the realm of humanitarian logistics.

4 - Forecast-driven collaborative repositioning optimization. An application to Madagascar

Birce Adsanver, Burcu Balçik, Valérie Bélanger, Marie-Ève Rancourt

Disasters are increasingly affecting human lives with greater frequency and severity over the years. Depending on the forecasting capabilities, it is possible to anticipate and mitigate the impacts of certain events. Anticipatory actions, also known as forecast-based early actions, play a crucial role in this regard by allowing humanitarian actors to take proactive measures before the disasters strike. This study focuses on a repositioning problem in anticipation of storms within a collaborative countrywide network. The network involves multiple humanitarian agencies that strategically preposition relief supplies across different regions. When a storm is anticipated to hit the country, the agencies begin receiving forecast updates providing predictions on storm conditions. They estimate disaster impacts by utilizing the available forecasts and relocate the prepositioned supplies to the potentially affected regions for a faster response. We address this problem by proposing an analytical approach that provides relocation recommendations based on the forecasts. We collaborate with the Emergency Supply Repositioning Group to design and integrate such a decision support tool into their "STOCKHOLM" platform, which offers prepositioned stock mapping and analyses to the stockholders. We test our approach and analyze the benefits of collaboration with a case study on Madagascar. The analyses are conducted by processing data related to the logistics network and storm forecasts.

at certain penetration levels. Irregular intraday electricity demand may cause overloads, thus increasing costs and decreasing quality. Appropriate charging pricing policies can be effective in reducing the imbalance in electricity demand. In this study, we examined the effects of fixed and time-of-use (TOU) pricing policies when users have different charging options. We developed a comprehensive simulation model to examine users' behavior in different charging option distributions. A Deep Reinforcement Learning (DRL) model is proposed to determine the pricing policy that offers the best price levels in terms of invariability of the intraday aggregate EV load profile. Our experiments in different charging option availability levels show that the TOU pricing schemes obtained from the proposed DRL model offer prices leading to more balanced load curves compared to fixed-price charging pricing. We also show that peak loads are more likely to occur when EV drivers have similar charging options. In these cases, generated TOU price tables reduce the standard deviation of the load profile more noticeably. This study is supported by TUBITAK under grant number 221M111.

2 - Management of electric vehicles to provide energy flexibility under uncertainty

Antoni Bosch Pons, Fernando García, Ferran Pinsach Batet, Lucía Igualada

In recent years, the adoption of Electric Vehicles (EVs) has increased, driven by government initiatives to require them to reduce greenhouse gas emissions. This increased adoption, while environmentally beneficial, has also led to an increase in electricity consumption. This paper analyses the advantages of bidirectional vehicle-to-grid (V2G) chargers for Charging Station Operators (CSOs): Electric Vehicles energy flexibility could be a valuable resource during grid congestion episodes. We analyze this flexibility by proposing a two-stage stochastic programming model under uncertainty, regarding the presence of EVs at charging stations. We utilize a mixed Long Short-Term Memory (LSTM) neural network to generate scenarios for each charger and then blend and reduce them into the most representative ones. We propose a large-scale optimization approach for solving the two-stage stochastic model. The use of a large-scale optimization approach helps to reduce the time for executing the optimal solution, which is beneficial to ensure management of grid variability. The results demonstrate that electric vehicles can provide demand flexibility, resulting in potential cost reductions and contributing to the prevention of power grid congestion during periods of low generation or high demand. Also, the developed solutions help to integrate renewable resources into the grid and reduce greenhouse gas emissions.

3 - Degradation-Conscious Charge Management: Comparison of Different Techniques to Include Battery Degradation in Electric Vehicle Charging Optimization

Ferran Pinsach Batet, Tomas Montes, Lucía Igualada, Josh Eichman

With the rise of battery electric vehicles and advancements in smart charging, there is potential to enhance flexibility and decrease charging expenses. However, degradation is often cited as a major concern for vehicle owners and must be considered. This paper focuses on unidirectional smart charging, often overlooked despite its prevalence. To do so, the authors proposed three kinds of Mixed Integer Linear Problems (MILPs): 1) implementing good usage practices, 2) two-steps direct evaluation of a semi-empirical battery degradation model, and 3) introducing economic weighting for charge rate and State of Charge degradation into the objective function. The objective function includes energy price arbitrage against retail tariffs and to increase realism, MILP models introduced minimum charging value and a maximum charging curve. Each of these models have different strengths and weaknesses which are explored in detail. The authors performed 384 scenarios, considering different charging time slots, initial State of Charge, State of Health, maximum delivering power, and energy price signal, all applied across 6 models. On average the adoption of smart strategies implied a total cost (energy bill plus battery degradation associated cost) reduction between 13.3% and 14.4%, compared with immediate charging. When comparing against a simple smart model without consideration for degradation, total cost improvements ranged between 0.9% and 1.4%.

Optimization for electric vehicles

Stream: Energy Management

Invited session

Chair: Miguel Anjos

1 - A TOU pricing approach for EV charging via DRL

Abdullah Kayacan, Mehmet Yasin Ulukus, Hatice Tekiner Mogulkoc, Engin Cicek, Murat Bilsel, Bahadır Tunaboşlu

Economic and ecological advantages make electric vehicles (EVs) more desirable than internal combustion engine vehicles. The charging need of EVs can have a critical impact on electricity distribution

4 - Optimal Electric Vehicle Charging with Dynamic Pricing, Customer Preferences and Power Peak Reduction

Miguel Anjos, Luce Brotcorne, Gaël Guillot

We consider a provider of electric vehicle charging that operates a network of charging stations and uses time-varying pricing to maximize profit and reduce the impact on the electric grid. We propose a bilevel model with a single leader and multiple disjoint followers. The customers (followers) makes decisions independently from each other. The provider (leader) sets the prices for each station at each time slot, and ensures there is enough energy to charge. The charging choice of each customer is represented by a combination of a preference list of (station, time) pairs and a reserve price. The proposed model takes thus into accounts for the heterogeneity of customers with respect to price sensitivity and charging preferences. We define a single level reformulation based on the reformulation for the rank pricing problem. Computational results highlight the efficiency of the new reformulation and the impact of the model on the grid peak.

Supply chain design in the circular economy

Stream: Circular Economy, Remanufacturing and Recycling

Invited session

Chair: *Andrea Tunì*

1 - Designing a closed-loop supply chain for wooden cable drums

Germán Paredes-Belmar, Franco Basso, Mariapaz Widow, Graciela González, Joaquín Ossandón

Closed-Loop Supply Chains (CSLCs) deal with the entire supply chain product cycle in both forward and reverse ways. This includes logistic operations such as handling, storing, and transporting recyclable products, waste, or packaging. This work focuses on a CLSC for Returnable Transport Items (RTIs) for packaging, inspired by a real-world case of a Chilean electrical conductor that uses wooden cable drums for product distribution. Currently, there is no plan for recovering or reusing this RTI. This study addresses this issue by considering both forward logistics and reverse logistics by reusing, recovering, or repairing the cable drums. A mixed-integer linear programming (MILP) model is designed to minimize the total costs of the CLSC while meeting demand and capacity constraints. The results show the convenience of adopting a CLSC approach, where it is possible to reduce costs by 30%-40% compared to using current forward logistics.

2 - Data-driven robust optimization of closed-loop supply chain design for household plastic waste

JunSeop Lee, Byung Do Chung

As household plastic products have become essential parts of our lives, increasing the plastic recycling rate is imperative. However, the global average recycling rate for plastic is remarkably low at 9%, and the low profitability of uncertain waste management is one of the major reasons. In this study, we developed a data-driven robust optimization model of closed-loop supply chain design to address the uncertain volume of plastic waste. Subsequently, we proposed a theorem capable of reformulating the worst-case of the uncertain public sectors model as a tractable model. Based on this proposed theorem, we have constructed a data driven robust bilevel optimization program to express decentralized decision-making between a manufacturer and public sectors. Conducting sensitivity analysis using real annual operational data, we confirmed that if public sectors adopt a conservative solution regarding uncertain plastic waste volume, it can lead to a decrease in manufacturer profit and a reduction in the plastic recycling rate. Furthermore, we found that if the manufacturer is concerned about fluctuations in

the purchasing price for plastic waste resulting from the conservative solution of public sectors, the manufacturer may attempt to purchase plastic waste from various regions.

3 - Large stochastic facility location problems for insulation waste treatment: Reduction-based solution techniques

Ruurd Buijs, Rob van der Mei, Elenka Dugundji, Sandjai Bhulai

The transition to the circular economy goes hand in hand with major redesigning challenges in manufacturing and logistics. Reverse supply chains form an important area of study within this context. The study of reverse supply chains touches upon many different disciplines, and from an Operations Research perspective provides interesting optimization problems. Our study concerns the reverse supply chain of insulation panels in the construction sector that contain rigid polyurethane foam (PUR). We examine a stochastic facility location model for locating treatment plants. Context specific constraints incorporating a cap on emissions and the economically rational behaviour of waste sorting companies are embedded into the model. Uncertainty affects the model, as the exact location and quantities of different types of insulation panels are not known exactly. Furthermore, some of the model parameters depend on future policy and advances in technology. For large buildings, we assume that the panels can be collected directly from the demolition site. As each of these buildings thus has an individual demand for collecting the material, both the model and the number of uncertain parameters to become very large. We investigate the performance of different methods of reducing the problem size for our model. We address methods to reduce the number of scenarios, and methods to reduce the number of demand points individually, and in synthesis with one another.

4 - Circular Supply Chain Design for Refurbishing Modular Products

Andrea Tunì, Nikoletta L Trivyza, Massimo Rapisarda

Circular supply chains are key enablers to implement the circular economy (CE), however they are yet to be established in industries with significant environmental impacts. Refurbishing is ranked high among circular strategies as it extends the lifespan of products and preserves product functionality across multiple lifecycles. Nevertheless, it requires a challenging coordination of forward and reverse supply chains. This work investigates the optimal circular supply chain re-design for the refurbishment of modular products under three scenarios: (i) cost minimisation, (ii) CO₂e emissions minimisation, (iii) cost and CO₂e emissions minimisation in an eco-efficient configuration. A mixed-integer linear programming model was developed and applied to a case study of a three-tiers global mining equipment supply chain, contextually determining the location of the refurbishment facilities. Findings highlight that supplier selection has a significant impact on the overall supply chain re-design, while locating the facilities in customers' proximity yields environmental benefits. This work contributes to the CE literature by designing optimal circular supply chains, which integrate a high-R imperative, such as refurbishing, while simultaneously considering product modularity, multimodal transportation, economic and environmental objectives. The model could further support practitioners aiming to re-design circular supply chains based on the refurbishment of modular products.

Sustainable Logistics

Stream: Sustainable Supply Chains

Invited session

Chair: *Chuanwen Dong*

1 - The impact of carbon tax on last-mile retail supply chain

Chuanwen Dong

This study proposes and analyzes a last-mile retail supply chain model. Consumers follow an Economic Order Quantity model to decide their quantity and frequency of shopping from the closest retail store. The retailer determines its store density to minimize the total logistics costs per unit of goods sold. In anticipation of the decisions from consumers and the retailer, the government imposes a carbon tax to reduce emissions. In contrast to the literature, we find that the impact of the carbon tax on the last-mile supply chain is not monotone. Depending on the parameters, a carbon tax may lead to a sparser or denser retail network. Surprisingly, there may even be a win-win scenario where a carbon tax incentivizes the retailer, who is primarily focused on cost minimization, to adopt a supply chain design that simultaneously minimizes costs and emissions (the win-win). Through numerical analysis using data from the United States and Germany, we find that denser last-mile retail networks are currently necessary to reduce emissions in both countries. The win-win scenario could potentially be achieved through, e.g., innovations in electrification.

2 - Optimizing City Logistics: Assessing the Efficiency of Integrated Water- and Land-based Transportation Systems

Cigdem Karademir, Breno Alves Beirigo, Bilge Atasoy

This study explores the efficiency of integrated water- and land-based transportation (IWLTL) systems in addressing the needs of growing urban populations. This has become more challenging under the regulations limiting the sizes and the reach of freight vehicles in cities to improve mobility and reduce carbon footprint. In the proposed systems, vessels can provide flexible and efficient means of transporting goods to supply light electric freight vehicles in the cities. The cost of an IWLTL system depends on the design of transshipment facilities, where goods are transferred from the water to the road network. Besides allocating resources in these facilities, this study also examines flexible IWLTL systems using public spaces as on-demand meeting points like parking areas and public transportation stops. Such systems introduce more complexity for the logistics services due to the interdependence between interacting vehicles requiring synchronization. We develop a decomposition model to formulate the optimization problems at both networks as well as at transshipment points under the real time resource capacities. Experiments on the benchmark instances show that on average, flexible IWLTL services provides a savings of 5% in terms of total travelled distances, 10% less on the roads with fewer vehicles and 30% more over waters, compared to the dedicated systems. Moreover, we assess these systems based on a case study we designed for a delivery service in Amsterdam, the Netherlands.

3 - Estimating the load consolidation potential for e-commerce deliveries in Austria - a scenario-based approach

Alexandra Anderlueh, Clemens Raffler, Julia Simhandl

The importance of online shopping has risen sharply in recent years. The Covid-19 pandemic brought up new customer segments, new industries and local shops were opened on a large scale by connecting to online retail. This leads to a significant increase in the volume of freight traffic. Various innovative approaches have already been tested, but most initiatives for cooperation between logistics service providers have not succeeded so far. Appeals to individual responsibility for bundling orders on the customer side also appear to be ineffective. Therefore, restructuring the commissioning process for delivery services could be the way to go. The idea of an independent online platform for the organization of logistics services could provide a one-stop-shop solution for these problems: instead of the current decentralized placing of delivery orders through individual dealers, deliveries could be centrally coordinated in the interests of the society and the environment. Hence, spatial, temporal as well as modal optimizations should be achievable. To evaluate the potential of such a solution the amount of load consolidation needs to be determined. A scenario-based approach is currently developed to derive appropriate estimates for Austria. First estimations show a reduction of greenhouse gas emissions caused by delivery vehicles of up to 20% for Austria in total but more detailed estimations are required to cover more realistic settings.

4 - Optimizing Downstream Logistics: Shipment Consolidation Strategies for Sustainable Supply Chains

Mahesh Gudipati, Ram Kumar, Ramesh Krishnan, Satyam Sahay

Global greenhouse gas (GHG) emissions in 2023 have crossed more than 58GT, and transportation is one of the key contributors to these emissions. Supply chain play an important role in efficiently moving goods from manufacturers to end customers. However, the traditional approach to supply chain management often results in excessive carbon dioxide (CO₂) emissions due to inefficient logistics processes. The supply chain landscape of automobile manufacturing organizations is characterized by complex networks involving multiple stakeholders, transportation modes, disparate inventory management systems, and complex supplier and dealer network. This complexity often leads to suboptimal transportation routes, underutilized capacity and excessive empty backhauls, all contributing to high CO₂ emissions. Addressing Scope 3 CO₂ emissions has become critical for organizations to align with sustainability goals. This paper attempts to address some of these challenges by focusing on shipment consolidation strategies to reduce the cost and GHG emissions in downstream logistics. By consolidating shipments, companies can streamline their distribution processes, reduce the number of vehicles on the road, and optimize delivery routes, leading to tangible reductions in CO₂ emissions. The presentation will discuss a case study from the automotive industry, illustrating the significant impact of time-based consolidation on emissions offering practical insights for academic and industry leaders.

Applications of combinatorial optimization II

Stream: Combinatorial Optimization

Invited session

Chair: [Antonio Alonso-Ayuso](#)

1 - Integrated Schedule Planning for Regional Airlines Using Column Generation

Alberto Santini, Vikrant Vaze

Medium-term airline schedule planning is traditionally tackled in a sequence of steps, including route selection, frequency planning, timetable design, fleet assignment, aircraft routing, crew scheduling, and tail assignment. Optimising each step separately is globally sub-optimal, but is often the only viable strategy because of the computational difficulty of solving the joint problem. This paper focuses on simultaneously optimising medium-term strategic decisions related to frequency planning, timetable design, and fleet assignment, as well as dealing with limited changes to the route selection process. Two conditions make this joint optimisation possible. First, we focus on the special case of regional airlines that work as feeder for larger mainline carriers. Second, we exploit a tight exponential-size formulation; we solve its continuous relaxation via column generation and obtain integer solutions via a restricted master heuristics. In this way, we obtain gaps consistently under 0.2%. An important characteristic of our approach is that it incorporates explicit passenger preferences via discrete choice modelling. Preliminary results on the network of Mesa Airlines and Republic Airways show a significant potential for increased profits and load factors. The main reason is a better synchronisation of feeder flights allowing for more connections and, thus, capturing a larger share of passengers whose itinerary involve two flights with a layover at the hub.

2 - Satellite Observation Scheduling Problem: an application on Mars Express mission

Benedetta Ferrari, Maxence Delorme, Manuel Iori, Marco Lippi, Roberto Orosei

In recent years, space exploration has received increasing attention, thus underlining the need for efficient management of space missions. Within this field, Satellite Observation Scheduling Problem (SOSP) concerns the scheduling of observations performed by satellites orbiting around Earth or other celestial bodies. The SOSP has been largely addressed in the last 30 years, dealing with both Earth-centered and outer space missions, with a lot of variants developed to cope with diverse applications and constraints. Our research focuses on the study of SOSP for the radar MARSIS onboard Mars Express mission, which observes the subsurface of Mars to map the presence of water. Specifically, the Mars Observation Scheduling Problem (MOSP) aims to optimally schedule MARSIS observations to reach a maximum quality coverage of the South Pole of Mars. The MOSP is of high difficulty and has been only manually solved until now. To solve the MOSP we use an approach combining machine learning and optimization. We first employ a neural network to predict the quality of future observations, starting from a massive historical dataset. We then look for the solution that maximizes the predicted quality by invoking different techniques, including an Integer Linear Program and a set of constructive heuristics and metaheuristic algorithms. The resulting algorithm is tested on several real-world instances and scenarios derived from the Mars Express mission, showing good performance.

3 - Robust Scheduling of Medical Appointments for Outpatients

Cristina Requejo, Marco Roma, Paola Cappanera, Maddalena Nonato, Marco Gavanelli

Chronic patients affected by Non-Communicable Diseases live at home, but often book appointments at a hospital for regular visits, tests or treatments according to their care pathway, which can integrate the medical protocols for several morbidities. It is good practice to schedule multiple services for the same patient on the same day, for the sake of a holistic approach to patient care. The services have a known duration and are partitioned by medical specialty; the operators are also partitioned and can provide all and only the services of their specialty. Services can be provided in any order, each operator can see only one patient at a time, and each patient can receive only one service at a time, without preemption. Since resources are limited, both in terms of operators and shifts, the goal of the problem is to schedule as many services as possible. However, the duration of a service is only an approximation and unexpected events, such as equipment failures or extra care for fragile patients, can delay its end time. Given a schedule, a delay propagates forward to all the subsequent services of the operator providing the service, as well as to the subsequent activities of the patient involved. Our main contributions are the formalization of a scheduling problem with limited operator shifts, and the methodological approach developed to deal with the uncertainty in the duration of services.

4 - 2D Variable Size Cutting Stock Problem: a real application in the honeycomb cardboard industry

Antonio Alonso-Ayuso, Paula Terán Viadero, F. Javier Martín-Campo

This contribution presents a linear mixed-integer optimization framework designed to tackle the two-dimensional variable-sized cutting stock problem (2D-VSCSP), particularly incorporating guillotine cuts. In the 2D-VSCSP, the objective extends beyond merely identifying cutting patterns; it involves determining optimal dimensions (width and length) for the panels to be manufactured, aiming to minimize material usage. The Cutting Stock Problems with Variable-Sized Stock were recently introduced in various sectors, notably the textile and cardboard industries. This paper introduces a model relevant to the cardboard industry, accommodating cutting patterns with multiple item types, a feature not previously explored. This enhances the model's flexibility and widens its range of applications. The impetus for this research stems from the honeycomb cardboard sector and is developed in collaboration with a company based in Spain. Furthermore, the model's effectiveness is validated using real-world data characterized by significant variability, demonstrating substantial reductions in material utilization compared to the company's current operational practices.

1 - Dynamic operator management in meta-heuristics using machine learning

Maryam Karimi Mamaghan, Mehrdad Mohammadi, Wout Dullaert, Daniele Vigo

This study addresses the impact of search operators on the performance of meta-heuristics. The efficient selection and management of operators from a diverse set are essential for optimization. Two key aspects are explored: portfolio selection, determining which subset of operators to consider at each search stage, and operator selection, deciding how to choose operators within that subset for each iteration.

A novel framework is developed to dynamically handle the portfolio of operators, incorporating the tabu concept and Q-learning. Unlike traditional static methods, this study focuses on creating an adaptive online portfolio. Acknowledging that not all operators are useful, the mechanism adds effective operators and excludes ineffective ones at different stages, optimizing overall performance. Inefficient operators are temporarily removed based on a tabu list size and may be reintroduced later. Additionally, new operators may be selectively included for specific search stages. Following portfolio selection, Q-learning dynamically chooses the most efficient operator for each iteration.

To evaluate the proposed framework, the permutation flowshop scheduling problem is tackled. Results demonstrate improvements in optimality gaps and convergence rates compared to offline portfolio selection and existing algorithms. The study highlights the efficacy of the dynamic approach in enhancing meta-heuristic performance and adaptability in complex optimization scenarios.

2 - New insights in hub location models

Mercedes Landete, Juan Manuel Muñoz-Ocaña, Juanjo Peiró, Antonio Manuel Rodríguez-Chia, Francisco Saldanha-da-Gama

In this work we present different advances in exact techniques for solving hub location problems. Firstly, we carry out the analysis of the classical model with path variables for multiple-allocation and we propose a new family of clique constraint. Some properties of the new inequalities and corresponding lifting are discussed, and a separation heuristic algorithm is proposed. A set of computational experiments are reported to evaluate the usefulness of the proposals when embedded in a commercial solver. The new family of inequalities is notably effective in r-allocation problems. Secondly, we propose a model for the single-allocation hub location problem with upgraded connections. In this case, the goal is to invest the budget both in reducing the cost of the network and in improving some of its connections. For this new model we propose an exact resolution algorithm based on the ordered median problem and on an existing approximation for large class of binary quadratic programs. In the computational analysis we compare the results for complete and incomplete hub networks. Finally, an analysis of the added-value of upgrading is conducted.

3 - Models for the Traveling Salesman Problem with Job-Time

Pablo Gutierrez, Carlos Contreras-Bolton

The traveling salesman problem with Job-Time (TSPJ) is a variant of the classic traveling salesman problem. In the TSPJ, the traveler visits a set of nodes, ensuring one visit to each of them while he initiates a job. The time of each job depends on the node where it is performed. Once started, the traveler moves to the next node, and the job continues autonomously. The aim is to minimize the maximum completion

time, also known as the makespan. However, since the problem is NP-hard, the existing mixed integer linear programming (MILP) models cannot be efficiently solved for medium and large instances. Therefore, we propose a new MILP model for the TSPJ, which is improved by the computation of valid lower and upper bounds. Moreover, we propose strengthened exponential-size formulations that explicitly incorporate subtour elimination constraints and additional valid inequalities. Based on the proposed model, we also develop an exact branch-and-cut (B&C) algorithm that is able to solve instances of the TSPJ. The new model and B&C algorithm are tested on benchmark symmetric instances from the literature, four sets of instances ranging in size from 17 to 1200 vertices. The computational results show that our B&C outperforms the state-of-the-art MILPs in the two smaller sets of instances. Meanwhile, for medium and large sets, our exact method achieves promising results for both instance sets.

4 - Optimizing Team Formation in Offshore Vendor Centers *Alexandros Baltas, Panagiotis Repousis, Theodoros Lappas*

In recent decades, the adoption of outsourcing to offshore vendors across various domains, such as software engineering and IT support, has grown significantly. Managing these vendors effectively, particularly in scenarios involving multiple cost centers, presents a range of challenges including issues of trust between vendors and clients, effective knowledge gathering and retention, cultural differences, and the impact of client organizational structures on team dynamics, and complex revenue considerations across cost centers. This paper extends the well known Team Formation Problem (TFP) that is focused on the formation of efficient teams based on skills and experience, by introducing a tailored variant for managing offshore vendors in multi-cost centre environments. We introduce a new mathematical model that accounts for multiple projects and clients, the varying expertise levels of workers and flexible definitions of team structures. The proposed model aims to optimize resource utilization and maximize throughput. Additionally, our research includes an experimental study employing synthetic datasets with varying sizes and characteristics to validate the applicability of our model in real-world scenarios.

1 - Balancing Realism and Simplicity: A Synthetic Dataset Approach for Comprehensive Model Benchmarking in Prescriptive Process Monitoring *Jakob De Moor*

Prescriptive Process Monitoring (PresPM) is an emerging field dedicated to devising methods for suggesting interventions in business processes to optimize them. Machine learning models are applied using event logs to attain desired outcomes for each case of a process. Current research in PresPM reveals two significant gaps. The first involves the underutilization of synthetic data in existing literature. Synthetic datasets offer easy customization and the ability to generate ground truth counterfactuals for a given case, providing precise model evaluation and explainability of an intervention recommendation. However, these datasets are often overlooked and can be unrealistic. The second gap revolves around the often exclusive focus on a narrow range of machine learning approaches and intervention types, restricting a holistic understanding of PresPM methodologies. To bridge these gaps, we conduct a thorough comparison of machine learning methods using a synthetic dataset mimicking a local bank's loan application process. This dataset strikes a balance between real-life complexity and simplicity, allowing meaningful comparisons. Our approach involves

variants of the established methods Causal Inference and (online) Reinforcement Learning and we compare insights obtained from the synthetic dataset with historical datasets to assess consistency when applied to real-world data. This research aims to contribute to a more comprehensive understanding of current methodologies.

2 - Approaches for multi-perspective trace clustering explainability

Yannis Bertrand, Jochen De Weerd, Estefanía Serral

IoT devices are often present around business processes (BPs), collecting data about parameters that have an impact on the process. E.g., the pressure in a tank can be a relevant aspect of the execution of a BP.

Trace clustering (TC) is used to group similar process instances, usually based on their sequential activity patterns. TC is often used to produce models describing different process variants discovered from separate clusters. However, TC can also be applied for exploratory data analysis (EDA).

This is particularly interesting in the context of multi-perspective BPs, which are surrounded with IoT devices. Multi-perspective TC (MPTC) can be used to group together cases with similar activity sequences and sensor data. However, explaining these clusters to process users then becomes more challenging.

To shed some light in the results of MPTC, we propose to use various complementary explainability approaches: 1) Partial dependency plots: they give a visual representation of the contribution of each perspective to the TC, and help users explore their clusters. 2) Permutation feature importance: give a more quantitative measure of the impact of each perspective, on the global TC. 3) Prototypes and criticisms: Show concrete instances and actively try to challenge TC results, showing the robustness of the clusters.

Each of these approaches focuses on a particular aspect of the MPTC, and supports a better understanding of the sources of variation of the BP.

3 - Introducing SuTraN: A Transformer-Based Encoder-Decoder Model for Enhanced Suffix Prediction in Business Process Monitoring

Brecht Wuyls

Predictive Process Monitoring (PPM) enhances the field of Process Mining (PM) by applying predictive analytics to forecast the future course of ongoing business processes. The prediction of suffixes, which involves predicting the sequence of forthcoming events, including their activity labels, timestamps, and remaining runtime, is particularly intricate. Present methodologies predominantly encounter two issues: firstly, they are predominantly trained to anticipate the next event, employing iterative feedback mechanisms for generating suffixes upon deployment—a strategy that not only introduces inaccuracies but also limits the exploitation of informative event attributes; secondly, the prevalent reliance on Long Short-Term Memory (LSTM) networks impedes their performance due to their inherent challenges with long-range dependencies and information loss over lengthy sequences. In response, this study unveils the Suffix Transformer Network (SuTraN), pioneering the use of an encoder-decoder Transformer framework for comprehensive suffix prediction in PPM. Tailored for this purpose, SuTraN innovatively forecasts complete event suffixes through a singular forward pass, eliminating the need for iterative loops and leveraging the full spectrum of event data without the constraints found in LSTM-dependent methods. Our evaluations, conducted on several real-world event logs, confirm that SuTraN delivers improved performance in suffix prediction relative to established methods.

1 - How to improve accessories sales forecasting of a medium-sized Swiss enterprise? A comparison between statistical methods and machine learning algorithms

Agneta Ramosaj, Nicolas Ramosaj, Marino Widmer

Forecasts accuracy is definitively a crucial topic for industrial companies. Indeed, its impacts are huge especially for finance and production departments. It can occur high costs for the company if the forecasts are not accurate, due to stock-outs or excesses of inventory, for example. Therefore, the purpose of this study is to optimize accessories forecasting for a medium-sized Swiss enterprise. To do that, different forecasting techniques are tested and a comparison is made between statistical methods and machine learning algorithms. The results have been adjusted thanks to the key account managers (KAM) expertise. In this talk, a comparison between exponential smoothing, seasonal autoregressive integrated moving average (SARIMA), SARIMAX (SARIMA with exogenous regressors) and Machine Learning algorithms such as k-nearest neighbors (k-NN), LASSO regression, linear regression and even random forest is presented. To compare these different methods, two measures of statistical dispersion are computed: mean absolute error (MAE) and root mean squared error (RMSE). These results have been standardized for a better comparison. It results that for our dataset SARIMAX (with the KAM's expertise as exogenous variable) gives better results than all the machine learning algorithms tested.

2 - How transport mode choices are influenced and what they mean for sustainable mobility: a data-driven study of the Asprela University Campus

Sayah Fooladi Mahani, Beatriz Brito Oliveira, Lia Patrício, Vera Miguéis, Maria Antónia Carravilla, José Fernando Oliveira

This study aims to investigate sustainable urban transportation in the Asprela Campus at Porto. This area was chosen because three universities and a hospital are located there, and also attracts a variety of travelers such as students, workers, and visitors. This allows the study to explore the different preferences and perceptions that shape urban transportation. The study analyzes the choices of urban transportation, such as public transit, micro-mobility, ride-hailing, and car-sharing, made by individuals aged 18 years or older who commute to the area for various purposes, such as work, study, hospital visits, and others. To gather the data, the survey was developed in three parts, the initial part asks how the importance of the factors affecting transportation mode choices, then asks about the specific modes used to access the area, and finally asks socio-demographic information. The survey's novelty is asking about factors affecting urban travel choices in the first part and examining actual behaviors in the second part, it gives a comprehensive view of urban transportation choices, closing the gap between preferences and real-world actions. The study's results can help mobility companies and policymakers improve multi-modal transportation and sustainable mobility. It also finds key factors for choosing urban transportation modes, which can assist in developing enhanced demand models for urban mobility design and strategic decisions.

3 - The dynamic travelling salesman problem with time-dependent and stochastic travel times: a deep reinforcement learning approach

Dawei Chen, Christina Imdahl, David Lai, Tom van Woensel

We introduce a novel approach using deep reinforcement learning to tackle the Dynamic Traveling Salesman Problem with Time-Dependent and Stochastic travel times (DTSP-TDS). The main goal is to dynamically plan the route with the shortest tour duration and visit all customers while considering the stochastic nature of travel times.

We employ a reinforcement learning approach to dynamically address the stochastic travel times to observe changing states and make decisions accordingly. Our reinforcement learning approach incorporates a Dynamic Graph Temporal Attention model that dynamically extracts information from the stochastic environment. We have tested the performance of our proposed approach on the simulation. Our approach can quickly provide high-quality solutions for all datasets using limited computing resources. The efficiency study on different models demonstrates that new components, such as the selection mechanism, dynamic attention component, and temporal pointer can improve the DGTA model. These findings highlight the importance of incorporating stochastic elements in the model to achieve better performance. Furthermore, the trained DGTA model exhibits generalization capability to different instances with varying customer locations and uncertainty levels of travel times without requiring additional training time. Our work contributes to advancing the field of DTSP-TDS, with potential applications in various industries, such as healthcare logistics.

4 - Evaluating diversion and treatment policies for opioid use disorder

Laura Albert

The United States (US) opioid crisis has led to over 840,000 fatalities since the 1990s. It has strained hospitals, treatment facilities, and law enforcement agencies due to the enormous resources and procedures needed to respond to the crisis. As a result, many individuals who use opioids never receive or finish the treatment they need and instead have many interactions with hospitals or the criminal justice system. This paper introduces a discrete event simulation model that evaluates three opioid use disorder treatment policies: arrest diversion, re-entry case management, and overdose diversion. Publicly available data from 2011 to 2019 in Dane County, Wisconsin (in the US), is used to forecast opioid-related outcomes through 2032. Through analyzing a variety of policy-mix implementations, this study offers a versatile framework for evaluating policies at various implementation levels. The results demonstrate that treatment policies that create new pathways and programming by utilizing treatment services and successfully divert at least 20% of eligible individuals can lead to more opioid-resilient communities and result in substantial savings.

1 - Fruit-based juice production process: a lot-sizing and scheduling problem

Deisemara Ferreira, Juan Sebastian Piñeros

This study deals with the planning and programming production problem of a fruit-based beverage company. This is a two-stage lot sizing and scheduling problem (tank and machine stages) with some specific features, such as a production buffer between the stages and a periodic clean-in-place (CIP) in each stage. Companies spend around 20% of the day cleaning line equipment. These features make this problem different of other beverage problems and includes additional difficulties to solve it.

This problem with these characteristics is difficult to solve for large real instances and has great applicability. Based on a mathematical model analytical methods are proposed, in order to support decision making in a more efficient way in the planning and lot sizing seeking to minimize the costs associated with production.

Computational tests were performed with instances found in the literature, based on real data, and with generated instances. The proposed methods were tested and the results were compared with the best method found in the literature for the problem under study.

Acknowledgments: This work was supported by the São Paulo Research Foundation (FAPESP) under Grants numbers 2023/08977-5, 2022/05803-3; the Brazilian National Council for Scientific and Technological Development (CNPq) under Grant number 315874/2021-0.

2 - Scheduling electricity distribution field maintenance by a prize-collection VRP approach

Roberto Tavares, Arineia Assis, Mario Batalha, Roberto Martins, Herick Morales

Daily field maintenance activities are common in a wide range of service providers and industrial applications. Electricity distribution systems are a classical example, commonly characterized by a set of pending services that must be accomplished by a set of maintenance teams. There are three main daily decisions usually involved in the scheduling of such services: (i) what services will be executed on a specified date; (ii) what is the sequence of each service list of each maintenance team (usually based on routing constraints); (iii) which team will execute each set of services. In this research, we address a real-world problem faced by an electricity distribution company. In this case, there are a set of activities available to the maintenance teams. For each activity is assigned a "prize" (strongly related to the activity's nature and deadline). The time required to start an activity may be influenced by the previous task (e.g., there is no need to perform two security checks on activities executed at the same place). This problem is faced as a derivation of the prize-collection vehicle routing problem (PCVRP). This research presents a MILP formulation and proposes a meta-heuristic approach to generate daily maintenance schedules. Both solution strategies are applied to problem datasets based on historical data of large cities attended by the electricity distribution company. Our results show the applicability of the meta-heuristic to solve this real-world problem.

3 - Control of pattern complexity in two-dimensional rectangular cutting problems

Maria Antônia Carravilla, Matheus Campinho, Elsa Silva, José Fernando Oliveira

Cutting and packing (C&P) problems are hard combinatorial optimization problems that arise in a variety of manufacturing and process industries. These problems arise whenever a larger object needs to be divided into smaller parts in order to minimise waste, and their optimal solution contributes to the reduction of raw material costs. However, many companies ignore optimisation approaches to their C&P problems in favour of production efficiency, preferring simple ways of cutting raw materials (cutting patterns), which require less human labour and less sophisticated and cheaper machinery, to complex, but in terms of raw material consumption optimised, cutting patterns. Therefore, it becomes critical to explicitly consider the impact of pattern complexity when solving C&P problems. In this talk, we will present a number of characteristics that influence pattern complexity, such as the number of different piece types, the total number of cuts, different types of strip structures, etc. Based on the floating-cuts mathematical model for two-dimensional rectangular cutting problems, these characteristics will be modelled, requiring new variables, additional constraints and resulting in new components of the objective function. Within a multi-objective optimisation framework, the conflicting objectives of waste and pattern complexity minimisation are addressed. Computational results are presented that show and quantify this trade-off. [Projeto CIBELE doi: 10.54499/2022.02767.PTDC]

4 - Solving Nesting Problems with Guillotine Cuts: A Novel Branch-and-Cut Algorithm

José Fernando Oliveira, Luiz Henrique Cherri, Adriana Cherri, Everton Fernandes da Silva

Cutting and packing problems have been studied for decades and the results of this research have a huge potential to improve many industrial production processes, both from an economic and environmental point of view. A widely studied problem is the two-dimensional irregular strip packing problem, aka nesting problem. This problem consists

of placing a set of two-dimensional irregular polygonal pieces on a board with a fixed height and a length long enough to be considered infinite. The classical objective is to minimise the length of the board used to cut all the pieces. The two-dimensional irregular packing problem has been tackled by both heuristic and exact methods, allowing or not the rotation of the pieces. Despite the diversity of papers on this problem, there is a lack of research on the generation of cutting patterns that satisfy the constraints of guillotine cutting for irregular items, which is fundamental in the glass cutting industry, and only heuristic methods were proposed to solve two-dimensional irregular cutting and packing problems with guillotine cuts. We will present an innovative branch-and-cut method to represent and exactly solve all variants of irregular cutting and packing problems with guillotine cuts that deal with a single board (aka as bin, plate or strip), namely the irregular strip packing problem, the irregular placement problem, the irregular knapsack problem, and the irregular identical item problem.

1 - Building, testing, analyzing, and debugging FICO Xpress Mosel projects

Susanne Heipcke, Yves Colombani

The Xpress Mosel language is used for implementing large optimization and analytics projects. Many such projects are deployed as Xpress Insight apps, either on individual software installations or in a cloud-based environment. To develop, build, deploy, and maintain such a large code base a team of OR specialists typically works in collaboration with other experts (UI specialists, problem domain experts). The availability of a suitable toolset for building, analyzing and testing the code in a largely automated way is a must nowadays. The Mosel distribution comes with a set of open-source tools supporting these development tasks. In this talk we review the roles and usage of the different tools to support the operation of enterprise-grade OR applications. We start with the build process (including the generation of online documentation), we then move on to the topics of testing and code analysis (profiling and coverage), and finally debugging. We consider in particular the case of Insight apps.

2 - GAMS Engine SaaS: A Cloud-Based Solution for Large-Scale Optimization Problems

Frederik Proske

GAMS Engine SaaS is a cloud-based service that allows users to run GAMS jobs on a scalable and flexible infrastructure, currently provided by Amazon Web Services (AWS). It was launched in early 2022 and has since attracted a variety of customers who benefit from its features, such as horizontal auto-scaling, instance sizing, zero maintenance, and simplified license handling. GAMS Engine SaaS is especially suitable for workloads that require large amounts of compute power and can be adapted to many different scenarios. In this presentation, we show a case study of a large international consultant agency that uses GAMS Engine SaaS to run Monte-Carlo simulations of a large energy system model in response to varying climate change scenarios. We describe how they leverage the GAMS Engine API to submit and monitor their jobs, how they select the appropriate instance type for each job, and how they can use custom non-GAMS code on Engine SaaS. We also discuss the challenges and benefits of using GAMS Engine SaaS for this type of application, and provide some insights into the future development of the service.

3 - AMPL: Advances in Python Integration, Cloud Deployment, and Open-Source Tools

Filipe Brandão

Python and its vast ecosystem are great for data pre-processing, solution analysis, and visualization, but Python's design as a general-purpose programming language makes it less than ideal for expressing the complex optimization problems typical of prescriptive analytics. AMPL is a declarative language that is designed for describing optimization problems and that integrates naturally with Python.

This presentation shows how the combination of AMPL modeling with Python environments and tools has made optimization software more natural to use, faster to run, and easier to integrate with enterprise systems. We demonstrate how AMPL and Python work together in a range of contexts:

- Installing AMPL and solvers as Python packages anywhere - Fast data transfer from/to Python data structures such as Pandas and Polars dataframes - Deploying models to the cloud quickly and easily

We also present our new open-source library for C/C++ and Python that makes it easy to connect modeling systems to AMPL-enabled solvers. In addition to our solver drivers, which have been open-source for many years, we are now offering open-source access to all of the deployment tools that we offer. Currently only AMPL takes full advantage of the functionalities that we provide, but the ability to solve problems using the full features of AMPL-enabled solvers is open to other systems as well.

4 - Advances in Automated Conversion of Optimization Problems

Christian Valente, Robert Fourer

We take it for granted that an optimization package accepts both minimization and maximization problems, recognizes them as equivalent, and converts all minimizations to maximizations (or vice-versa) before solving. This is only the very simplest example of the many conversions carried out routinely by large-scale optimization software. The range of expressions recognized by modeling languages and solvers has been steadily extended in ways that make optimization models easier to describe, validate, and maintain — but that make conversion possibilities ever more numerous and complex.

Continuing this trend, automatic conversions have been a central feature in the design of a new solver interface framework for the AMPL modeling language. This presentation describes a range of challenges that have been faced in detecting formulations that solvers can handle, and in implementing conversions to forms that solvers require. Examples combining a variety of discrete and nonlinear expressions lead to some general recommendations for design and implementation of automated conversions.

demonstrated on wage data from the Czech Republic. For the construction of mixtures, it is possible to use densities of classical distributions for modelling wage data such as normal, logarithmic normal, Johnson's and other distributions. When creating the final mixture, we solve two problems. First, we need to determine the number of components in the mixture. Secondly, we need to estimate the parameters of individual densities in the mixture. Since we have a large amount of data broken down by different criteria (age, gender, region, education, etc.), we can naturally divide the data into a large number of categories. Each category is then represented by one component in the resulting mixture. Detailed data breakdown allows us to calculate weights of individual components in the resulting mixture. In addition to the classic procedure known from theory, the authors in the article also offer a non-standard approach, which allows not only to model the course of past data, but also the possibility of estimating the future development of the wage distribution. In the conclusion, attention is also paid to the stability of the models.

2 - GIMI: Generative iterative multiple imputation for improving health trajectory estimation in the ICU

Anahita Khojandi, Matt Baucum, Senne Van Steelandt, Rama Vasudevan, Robert Davis, Nadeem Shafi

As the field of precision medicine grows, accurately forecasting patients' health trajectories is essential for developing data-driven treatment models. Yet researchers must still contend with high levels of missingness due to issues such as missed bedside readings, data entry error, or in the case of outpatient monitoring, inconsistent patient follow-ups. When forecasting patient health trajectories, even small imputation errors can compound over the given time horizon, complicating the task of missing data imputation and jeopardizing model accuracy. To address this, we develop a novel on-training imputation algorithm - Generative Iterative Multiple Imputation (GIMI) - which estimates missing health data by directly maximizing the accuracy of patients' predicted health trajectories. Rather than separating the imputation and forecasting steps, GIMI leverages state-of-the-art generative neural networks to simultaneously forecast patients' missing and observed health trajectories, and is trained in an end-to-end fashion to maximize forecast accuracy. Using a large clinical dataset of intensive care unit (ICU) patients, we show that GIMI outperforms commonly used benchmarks in forecasting patient health trajectories in the presence of missing data. Notably, we show that the imputation errors of several existing imputation techniques compound over the health trajectory time horizon, whereas GIMI's prediction accuracy remains stable.

3 - Analysis of characteristics of human score and improvement of feedback of evaluation results of automated essay scoring system

Megumi Yamamoto

We propose and construct an automated essay scoring system based on rubric to reduce the workload on teachers. This system calculates thirteen items, including written content, document style, writing skills, and output the overall evaluation results. We collected and analyzed human score data to improve accuracy of overall evaluation. Specifically, we asked 6 faculty members to score 25 essays manually using our automated scoring system rubric to identify the characteristics of items that affect the overall evaluation. The results revealed that low-rated essays had similar evaluation results among faculty members. Correlations were also obtained between the automated and human scores for document style, skill, and contents among the rubric items. However, we could not obtain the common evaluation items among the teachers for high-rated essays and established the absence of an effective automatic calculation method for the overall evaluation. Therefore, we classify low-rated essays and others using the accumulated low-rated essay data and present a comprehensive evaluation of low-rated essays by automated scoring. On the other hand, for others including high-rated essays we suggest that a feedback system highlighting essential evaluation contents rather than the overall evaluation would be beneficial.

1 - Probability models based on a mixture of densities

Lubos Marek

When we build the model of probability distributions, we can work with one distribution or use a mixture of distributions. In general practice, one density distribution is usually used. We will show another approach, using a mixture of distributions. The whole process will be

4 - Analysis of the implementation of digitisation in human resource management depending on the size of the organisation or economic sector

Terezie Krestová

Digital transformation has become a worldwide phenomenon and has a significant impact on the functioning of organisations in many areas. In our research, we focus on the application of digitisation in the field of human resource (HR) management. There are many possibilities for utilising digitisation in HR, e.g., employee recruitment, more efficient planning of interviews, productivity measurement, psychodiagnostics tests, adaptation of new employees, and other areas. A questionnaire has been developed to determine i) the extent to which digitisation is implemented in organisations in the Czech Republic, ii) which specific elements of digitisation are used, iii) what consequences organisations observe in this context, and iv) whether barriers to the introduction and implementation of digitisation are observed in relation to the age of employees. Statistical methods are used for analysis in which we focus on whether the implementation of digitisation varies depending on the size of the organisation or the economic sector. Attention is also paid to whether it can be argued that the benefits of digitisation increase disproportionately when implemented in multiple areas. We employ the GUHA method to discover the knowledge from the data and generate statistical hypotheses. Hypotheses are tested by means of the chi-square test. Additionally, selected multidimensional statistical methods, such as factor or cluster analysis, are also applied to evaluate the obtained results.

Chair: *Gerardo Toraldo*

1 - Bilevel learning optimization and applications

Serena Crisci

Bilevel optimization has gained a lot of attention in recent years as a data-driven learning technique for the estimation of unknown model operators or for the automatic selection of hyperparameters in highly parameterized models. Formally, a bilevel problem consists in a nested optimization problem where a variational model acts as a constraint. Starting from an outline of the main theoretical concepts of bilevel formulations, in this talk numerical bilevel schemes to address imaging and portfolio optimization problems will be analysed, combined with different strategies to properly derive the gradient of the upper-level loss, which is one of the major obstacle in bilevel optimization. Numerical tests will be presented to validate the proposed schemes.

2 - Nonsmooth optimization in sparse portfolio selection

Zelda Marino, Stefania Corsaro, Valentina De Simone

In this talk we describe a fused lasso approach for the regularized multi-period mean variance model, in a Markowitz framework. Multi-period portfolio selection aims at computing the optimal allocation of wealth among n assets within a time horizon of m periods. In addition, the investor can rebalance the portfolio at the beginning of each period. We define a multi-period minimum variance model with final expected return and introduce ℓ_1 -regularization techniques to stabilize the solution process, which is well-known to be ill-conditioned because of assets correlation. Two ℓ_1 -penalty terms are used: one on portfolio weights promotes sparsity in the solution; this allows investor to reduce both the number of positions to be monitored and the transaction costs. A second ℓ_1 -penalty term is added to the objective function of

the arising optimization problem. This is a penalization on the portfolio turnover, thus it limits the number of transactions by preserving the pattern of active positions. The model leads to a nonsmooth constrained optimization problem, where the inequality constraints are aimed to guarantee at least a minimum level of expected wealth at each date. We develop iterative algorithms based on first order methods. We validate the approach showing results of tests performed on real data.

3 - Parallel computing in optimization methods used in estimating risk-neutral densities through option prices

Antonio Santos, Ana Monteiro

Option pricing is an active area of research in financial economics. The risk-neutral density is a critical element in pricing derivative assets, and it can be estimated using nonparametric kernel methods. Recent research considered large-scale optimization problems, which significantly improved the robustness of estimating risk-neutral densities through observed option prices. In nonparametric estimation methods, kernel bandwidth estimates are crucial elements. However, they also represent the most computational challenge in implementing such methods, namely when large-scale optimization problems are used in curve fitting. Some of the computational challenges can be solved by considering parallel computing algorithms performed using Graphical Processing Units. We propose a tailor-made Cross-Validation criterion function to define optimal bandwidths (two parameters) associated with the risk-neutral estimation problem, defined through an optimization problem with non-convex objective functions. By implementing a grid-search approach within a big data scenario and through a large-scale optimization problem, computational times can be prohibitive for applying these methods in real-time decision-making. Parallel computing methods within a grid-search optimization algorithm substantially reduce computational times, allowing for more effective decision-making processes related to risk-neutral density estimation and option pricing.

1 - Should forests be restored by producers or deforesters?

Fouad El Ouardighi

A non-cooperative model is formulated where a producer and a deforester generate polluting emissions over time. Given the benchmark provided by the cooperative solution, we investigate two scenarios i) whether the forest's restoration should be done by the deforester alone (as the forest's owner) or outsourced to the producer (the forest's non-owner), and ii) whether non-cooperative strategies for either of these two scenarios can eliminate history dependency.

2 - Maximizing algal productivity in raceway ponds for bioenergy generation: A mathematical perspective

Aurea Martinez, Lino J. Alvarez-Vazquez, Rodriguez Carmen, Miguel E. Vazquez-Mendez

We propose a novel mathematical methodology to accomplish the optimal performance of a raceway: an open-channel pond where circulating wastewater is used for the cultivation of algae that will be employed as source in bioenergy production. Algal productivity maximization is addressed here by means of optimal control techniques for partial differential equations. So, we first introduce a rigorously detailed mathematical formulation of the control problem, based on a coupling of the hydrodynamical equations with the system for algal concentration.

Then, we suggest a full numerical algorithm for its computational resolution, and finally we show some preliminary results related to the numerical optimization of the problem.

3 - A stationary equilibrium model of green technology adoption with endogenous carbon price

Giorgio Ferrari

We propose and analyze a stationary equilibrium model for a competitive industry which endogenously determines the carbon price necessary to achieve a given emission target. In the model, firms are identified by their level of technology and make production, entry, and abatement decisions. Polluting firms are subject to a carbon price and abatement is formulated as an irreversible investment, which entails a sunk cost and results into switching to a carbon neutral technology. In equilibrium, we identify a carbon price and a stationary distribution of incumbent, polluting firms, that guarantee the compliance with a certain emission target. Our general theoretical framework is complemented with a case study with Brownian technology shocks, in which we discuss some implications of our model. We observe that a carbon pricing system alongside installation subsidies and tax benefits for green firms trigger earlier investment, while higher income taxes for polluting firms may be distorting. Moreover, we discuss the role of a welfare maximizing regulator, who, by optimally setting the emission target, may mitigate or revert some parameters' effects observed in the model with fixed limit. This is joint work with Felix Dammann.

4 - Optimal Sustainable Investments in a Multi-Objective Dynamic Model of the Firm

Andrea Seidl, Richard Hartl, Peter Kort

Reducing pollution is something desirable for a firm, however, sometimes this is only achievable by means of reducing production which in turn has a negative impact on revenues. In the present talk, we consider a simple two-objective optimal control problem. We discuss the advantage of using the epsilon-constraint method to determine the Pareto front as opposed to the conventional weighted-sum approach. We are able to derive analytic results for our optimal control problem and discuss their implications.

1 - ML-based Adaptive Risk Parameters Tuning for Robust Optimization

Emanuele Pizzari, Marco Boresta, Diego Maria Pinto

This paper introduces a novel approach that integrates Robust Optimization with Machine Learning (ML) to dynamically estimate optimal risk parameter values for uncertain environments. By leveraging historical data and engineering informative features, we train an ML model to predict risk protection values tailored to each instance's characteristics. Unlike static approaches, our method offers adaptability and enhances decision-making in uncertain domains. Through experimentation, we demonstrate the efficacy of our approach in improving robustness and performance.

2 - Coalitional Acceptability Games: A Framework for Risk-averse Stochastic Coalitional Games

David Wozabal, Walter Gutjahr, Raimund Kovacevic

We study the problem of coalition formation and profit sharing among risk-averse agents who jointly undertake a project which requires management decisions and leads to uncertain outcomes. We use acceptability functionals to model the agents' risk preferences and define the value of coalitions by the optimized sup-convolution of their acceptability functionals. We call such games coalitional acceptability games and provide conditions for the non-emptiness of the core for important subclasses of games such as network games, bankruptcy games, and generalized production games. We show that players agree on ex-ante contracts that are equivalent to a mutual exchange of standard options contracts. Finally, we illustrate our approach with two numerical examples: a water management application and a detailed case study of a virtual power plant.

3 - Index policy for multiarmed bandit problem with dynamic risk measures

Ozlem Cavus, Milad Malekipirbazari

The multiarmed bandit problem (MAB) is a classic problem in which a finite amount of resources must be allocated among competing choices with the aim of identifying a policy that maximizes the expected total reward. The classical MAB makes the strong assumption that the decision maker is risk-neutral and indifferent to the variability of the outcome. However, in many real life applications, these assumptions are not met and decision makers are risk-averse. Motivated to resolve this, we study risk-averse control of the multiarmed bandit problem in regard to the concept of dynamic coherent risk measures to determine a policy with the best risk-adjusted total discounted return. In respect of this specific setting, we present a theoretical analysis based on Whittle's retirement problem and propose a priority-index policy that reduces to the Gittins index when the level of risk-aversion converges to zero. We generalize the restart formulation of the Gittins index to effectively compute these risk-averse allocation indices. Numerical results exhibit the excellent performance of this heuristic approach. Our experimental studies suggest that there is no guarantee that an index-based optimal policy exists for the risk-averse problem. Nonetheless, our risk-averse allocation indices can achieve optimal or near-optimal policies which in some instances are easier to interpret compared to the exact optimal policy.

4 - A Data-Driven Methodology for Contextual Unit Commitment Using Regression Residuals

Guzin Bayraksan, Ogun Yurdakul

We present a data-driven approach that integrates machine learning prediction models with optimization under uncertainty in the presence of contextual information by utilizing residuals from the learning models. We discuss an application of this approach for making unit commitment decisions under uncertain net load conditions to improve short-term power system operations. We propose several enhancements to the basic methodology and assess their effectiveness on several case studies conducted using real-world data collected from the California and New York Independent system operators. Results show that the proposed approach can significantly improve the out-of-sample performance.

Game Theory, Solutions and Structures VI

Stream: Game Theory, Solutions and Structures

Invited session

Chair: *László Kóczy*

1 - Clustering prevention games on signed networks

Maria Serna, Xavier Molinero, Fabian Riquelme

Signed networks are graphs in which each edge has associated a sign. They were introduced as a simplified model to analyze social relationships. A positive sign in an interaction represents friendship while a negative one means animosity. Central notions in signed networks relate to the possibility of partition the vertices into clusters so that the positive edges join vertices in the same cluster and the negative edges join vertices in different clusters. This leads to two relevant notions: structural balance (having such a partition into two clusters) and social equilibrium (having such a partition). We study signed graphs with respect to these two notions from the point of view of cooperative game theory. We first introduce some new families of simple games on signed network and analyze several parameters and properties. We compare them to the ones known for other subclasses of simple games, in particular with social disruption games which were introduced regarding social equilibrium. In addition, we give some complexity results on the considered properties.

[Supported by Spanish AEI grant MICINN PID2020-112581GB-C21]

2 - Cooperative game theory and cost allocation: the case of renewable energy

Mariam Sangare

A renewable energy community is a non-profit legal entity involving prosumers which produce, consume, and exchange energy. In these communities, prosumers can cooperate to maximize the community's social welfare. In practice, this naturally raises the question of the community's social welfare sharing, as the members may have different contributions to the social welfare. In this presentation, we first empirically highlight the benefits of cooperation for the community and the individual members. Then, we present some cost-sharing mechanisms (from the literature) that guarantee the stability of the grand coalition of the prosumers in the community. Finally, we present some results on instances built with real-world data from our partner's demonstrator, Smart Lou Quila, located in South France.

3 - Properties and parameters of social disruption games

Xavier Molinero, Fabian Riquelme, Salvador Roura, Maria Serna

Signed graphs are extensively used across various real-world social networks, where positive edges represent favourable relationships (friends, colleagues) and negative edges denote unfavourable ones (enemies, adversaries). Some previous research in signed graphs has focused on defining properties to evaluate clustering tendencies in the sense that the positive edges join vertices in the same cluster and the negative edges join vertices in different clusters. This work gives theoretical and experimental results of the so-called social disruption games. These games form a subclass of the simple games defined in the classical game theory. Social disruption games satisfies that a set of vertices is a winning coalition if and only if the subgraph induced by the coalition contains a cycle with only one negative edge. In this work, we explore properties such as properness, strongness, and decisiveness, among others. We also give some results on parameters like length, width, strict length, and strict width, etc. Finally, we present signed graphs that define social disruption games with specific properties and parameters (vetoers, critical players, symmetric players, etc.).

[Supported by Spanish AEI grant MICINN PID2020-112581GB-C21]

4 - One Man, One Vote, One Price

László Kóczy, Balázs R. Sziklai

Originally introduced to allocate parliamentary seats among states or provinces, apportionment methods can distribute any scarce discrete resource based on a series of claims or budgets. Here, we focus on the price of representation: how one can turn the claims, such as the number of voters, into a share of the resource, such as the parliamentary seats. The D'Hondt method naturally emerges as a competitive equilibrium. We show that the class of parametric divisor methods is fully characterised by a competitive equilibrium augmented by a uniform credit or debt with respect to the original claims.

While in a competitive equilibrium, all pay the same price, states or provinces are not equally efficient at converting their claims. Optimization apportionment methods such as the Leximin focus on minimizing price differences. We demonstrate how the D'Hondt and Adams methods can be formulated as optimization methods and highlight their connection to the Leximin method.

Advances in Continuous Multiobjective Optimization

Stream: Multiobjective Optimization

Invited session

Chair: *Firdevs Ulus*

1 - A multiobjective continuation method to compute the regularization path of deep neural networks

Augustina Chidinma Amakor, Sebastian Peitz

Sparsity is a highly desired feature in deep neural networks (DNNs) since it ensures numerical efficiency, improves the interpretability of models (due to the smaller number of relevant features), and robustness. In machine learning approaches based on linear models, it is well known that there exists a connecting path between the sparsest solution in terms of the L1 norm (i.e., zero weights) and the non-regularized solution, which is called the regularization path. Very recently, there was a first attempt to extend the concept of regularization paths to DNNs by means of treating the empirical loss and sparsity (L1 norm) as two conflicting criteria and solving the resulting multiobjective optimization problem. However, due to the non-smoothness of the L1 norm and the high number of parameters, this approach is not very efficient from a computational perspective. To overcome this limitation, we present an algorithm that allows for the approximation of the entire Pareto front for the above-mentioned objectives in a very efficient manner. We present numerical examples using both deterministic and stochastic gradients. We furthermore demonstrate that knowledge of the regularization path allows for a well-generalizing network parametrization.

2 - Multi-Objective Nonlinear Conjugate Gradient Schemes with Guaranteed Descent

Manuel Berkemeier, Sebastian Peitz

Various nonlinear Conjugate Gradient (CG) schemes have been observed to improve convergence rates in single-objective optimization compared to steepest descent, without requiring second-order derivatives. Pérez and Prudente translated many of the most popular CG directions to the multi-objective case. However, in order to prove convergence, the classical CG schemes require us to assume Wolfe conditions on the step-size. In some settings, fulfilling Wolfe conditions might not be possible. Thus, we present several example directions that provide guaranteed descent in all objective functions, independent of the step-size. This enables us to prove convergence to Pareto-critical points for a simple inexact line-search algorithm with backtracking to satisfy some modified Armijo-rule. Our special CG directions are designed to be implementable without too much computational cost, and numerical experiments show the efficacy of the algorithm.

3 - A Bi-Objective Optimization Based Acquisition Strategy for Batch Bayesian Global Optimization

Pierluigi Mansueto, Francesco Carciaghi, Simone Magistri, Fabio Schoen

In this work, we deal with batch Bayesian Optimization problems over a box and we propose a novel bi-objective optimization (BOO) acquisition strategy to sample points where to evaluate the objective function. The BOO problem involves the Gaussian Process posterior mean and variance functions, which, in most of the acquisition strategies from the literature, are generally used in combination, frequently through scalarization. However, such scalarization could compromise

the Bayes-Opt process performance, as getting the desired trade-off between exploration and exploitation is not trivial in most cases. We instead aim to reconstruct the Pareto front of the BOO problem based on optimizing both the posterior mean as well as the variance, thus generating multiple trade-offs without any a priori knowledge. We then propose two possible methodologies to select potentially optimal points from the Pareto front. Our methodology is finally tested with well-known acquisition strategies from the literature, in order to highlight its effectiveness on different settings.

4 - Vector exponential penalty E-function method for E-differentiable vector optimization problems

Najeeb Abdulaleem

In this paper, a new concept of generalized convexity is introduced for E-differentiable vector optimization problems. The concept of E-r-invexity is introduced as a generalization of the invexity notion. Further, a new vector exponential penalty E-function method for E-differentiable vector optimization problems is introduced. Furthermore, this work presents an investigation into two methods for solving multiobjective programming problems. First, it explores a sequence of vector penalized optimization problems utilizing a vector exponential penalty E-function. The convergence of this method is established. Next, it defines and analyzes the exactness property of a vector exact penalty E-function method within the context of the introduced vector exponential penalty E-function method. Conditions are provided to ensure the equivalence of sets of (weak) E-Pareto solutions between the original E-differentiable optimization problem and the associated vector E-penalized optimization problem using the vector exact exponential penalty E-function. This equivalence is established for E-differentiable vector optimization problems involving E-r-invex functions.

Advances in Complex and Real Semidefinite Programming

Stream: Conic Optimization: Theory, Algorithms, and Applications

Invited session

Chair: Renata Sotirov

1 - Semidefinite liftings for the complex cut polytope

Lennart Sinjorgo, Renata Sotirov, Miguel Anjos

We consider the complex cut polytope: the convex hull of Hermitian rank-one matrices xx^* , where the elements of the n -dimensional vector x are complex m -th unit roots. These polytopes find applications in MAX-3-CUT, digital communication, and more generally, complex quadratic programming. For $m = 2$, the complex cut polytope corresponds to the well-known real cut polytope. We provide an exact description of the complex cut polytope for $m = n = 3$ and investigate second order semidefinite liftings of the complex cut polytope. For such second order liftings, we show a method for reducing the size of the matrix, without weakening the approximation. We support our theoretical findings with numerical experiments.

2 - Semidefinite programming by projective cutting planes

Daniel Porumbel

We consider the most standard SDP (semidefinite programming) program in a cutting-planes setting, i.e., the program is formulated using the infinitely-many linear cuts that define the SDP cone. We go beyond the most classical approach that relies on repeated separation; to separate a matrix X is enough to test if its minimum eigenvalue is above or below zero. Instead, we upgrade the separation sub-problem to a projection sub-problem: given a feasible matrix X in the SDP cone

and an arbitrary direction D , what is the maximum t such that $X+tD$ stays in the SDP cone? This new sub-problem enabled the new algorithm to converge to the optimal solution through a sequence of both inner and outer solutions (with regards to the SDP cone). The general Projective-Cutting-Planes logic was first proposed in a purely linear context [Daniel Porumbel, Projective Cutting-Planes, SIAM Journal on Optimization, 30(1): 1007-1032, 2020]. We will show that the projection sub-problem can also be solved very efficiently in a new SDP context. One way to solve it would be to compute the generalized eigenvalues of X and $-D$. But we seek maximum speed and we solve it using certain factorizations suitably tailored to our given context. Results suggest that the overall method may be very competitive (compared to Mosek or ConicBundle) for matrix sizes larger than 2000×2000 . It is less competitive if the matrix size is low and if the initial program has many linear constraints.

3 - Semidefinite approximations for bicliques and biindependent pairs

Sven Polak, Monique Laurent, Luis Felipe Vargas

Let G be a bipartite graph with vertex color classes V_1 and V_2 . A biindependent pair in G is a pair (A, B) , where $A \subseteq V_1$, $B \subseteq V_2$ and the union $A \cup B$ is an independent set. We consider the following three parameters $\alpha(G)$, $\beta(G)$ and $\gamma(G)$, that are defined, respectively, as the maximum sum $|A| + |B|$, the maximum product $|A| \cdot |B|$ and the maximum ratio $(|A| \cdot |B|) / (|A| + |B|)$, taken over all biindependent pairs (A, B) in G .

Similar parameters can be defined for bicliques in general graphs, which can however be reduced to the above parameters in bipartite graphs. While $\alpha(G)$ is easy to compute in bipartite graphs, Peeters (2003) showed that computing $\beta(G)$ is an NP-hard problem. The parameter $\gamma(G)$ was introduced by Vallentin (2021). The parameters $\beta(G)$ and $\gamma(G)$ have many applications, in particular, to bounding product-free subsets in finite groups, and the nonnegative rank of nonnegative matrices.

We investigate SDP upper bounds on $\beta(G)$ and $\gamma(G)$, which can be seen as variations of the Lov'asz ϑ -number. We show links among them as well as with an earlier parameter by Haemers (2001), and we formulate closed-form eigenvalue bounds. We also show that computing $\gamma(G)$ is NP-hard, by showing that it is NP-hard to determine if a bipartite graph has a biindependent pair (A, B) with $|A| + |B| = \alpha(G)$ and $|A| = |B|$. We finally present a conjecture about the value of $\gamma(G)$ on the hypercube graph.

Stochastic Models in Logistics

Stream: Stochastic Modelling

Invited session

Chair: Caroline Spieckermann

1 - Inventory Planning with Supply Yield Uncertainty: On the Optimality of Linear Inflation Rules

Jan Van Mieghem, Riccardo Mogre

We study inventory planning under demand and supply yield uncertainty. We present new optimality conditions and explicit solutions for the associated single-period "newsvendor" model. In general, the stochastic-optimal order policy is non-linear in the starting inventory level s . The literature has proposed Linear Inflation Rules (LIR) that inflate the classic order-up-to policy. We prove that LIR are only stochastically optimal in the degenerate setting where either demand or (not and) supply yield is uncertain.

Given the good performance of LIR we investigate their optimality under two robust formulations and provide bounds. We prove that LIR

are robustly optimal when only the support of the demand and supply yield distributions are known. Yet we also provide the optimal distribution-free policy when the first two moments of those distributions are known, which again is non-linear. Both models provide novel, explicit order rules that may be useful for dynamic inventory control.

2 - Analysis of a flexible order quantity contract in a newsvendor setting

Dimitrios Pandelis, George Kozanidis

We consider a newsvendor model with a retailer facing random demand and a primary supplier characterized by random capacity. The probability distributions of both the demand and the capacity are assumed to be known. The retailer places an order, which may not be satisfied in full because the quantity that can be delivered is capped by the capacity of the supplier. In order to mitigate this supply risk, the retailer places an order to a second supplier, which is reliable but more expensive, under a contract according to which he is allowed to return a portion of the order after the delivery by the primary supplier. We also assume that this option must be exercised before the realization of the demand. We characterize the optimal orders to the two suppliers and present numerical results that provide interesting insights into the effect of various model parameters on these optimal quantities.

3 - The bullwhip effect with correlated lead times and auto-correlated demand

Zbigniew Michna, Stephen Disney, Peter Nielsen

We quantify the bullwhip effect (which measures how the variance of replenishment orders is amplified as the orders move up the supply chain) when demands constitute a first-order auto-regressive random process and lead times constitute a possibly temporally correlated stationary sequence of random variables. We assume future demands are predicted with the minimum mean squared error method and random lead times are estimated using any method. Under these general assumptions we derive a formula for the bullwhip effect measure as the ratio of the replenishment orders variance and demands variance. Using this formula we analyse the impact of auto-correlated demands and auto-correlated lead times on the bullwhip effect. Our investigation of the impact of the lead time auto-correlation on bullwhip appears to be unique in the literature. Our analysis focuses on using the naive forecasting method, the moving average method and the minimum mean squared error method for forecasting the lead times. We show how the bullwhip effect is influenced by demand auto-correlation, lead time auto-correlation, and number of periods in the moving average forecast of the lead times. We reveal that there exists minima and maxima in bullwhip effect as a function of those parameters. For the moving average forecasting method of lead times and their negative auto-correlation we observe an even-odd phenomenon. Our theoretical results are confirmed by Monte Carlo simulation.

4 - Explorable Uncertainty in Routing

Caroline Spieckermann, Christoph Kerscher, Stefan Minner

Planning in logistics and transportation is oftentimes complicated by a high degree of uncertainty about the actual travel distances, times, or costs. While stochastic optimization is concerned with making optimal decisions under such uncertainty, it disregards that in many practical applications, uncertainty can be reduced upfront through research and tests, also known as "explorable uncertainty". However, while uncertainty reduction through exploration can improve decision-making, it oftentimes comes at a cost, and one needs to balance exploration costs and solution quality. We study the vehicle routing problem with time windows (VRPTW) and stochastic travel times where uncertainty about travel times can be reduced by making queries to a traffic data provider while respecting an overall querying budget. This converts the stochastic VRPTW into a partially deterministic problem that we solve via point-based approximation and sample average approximation to deal with the remaining uncertainty. We present different methods to make good and fast querying decisions based on statistical features and learning and show their effectiveness in an extensive numerical study. By assuming different degrees of uncertainty, correlations, and time-window restrictions, we give detailed insights into the value of uncertainty exploration in routing.

Reinforcement Learning: Methods and Applications

Stream: Advances in Stochastic Modelling and Learning Methods

Invited session

Chair: *Konstantin Avrachenkov*

1 - Influence Maximization in Dynamic Networks Using Reinforcement Learning

Seyedehhaleh Seyeddzaji, Konstantin Avrachenkov

Influence maximization (IM) has been widely studied in recent decades, aiming to maximize the spread of influence over networks. Despite many works for static networks, fewer research studies have been dedicated to the IM problem for dynamic networks, which creates many challenges. An IM method for such an environment, should consider its dynamics and perform well under different network structures. To fulfill this objective, more computations are required. Hence, an IM approach should be efficient enough to be applicable for the ever-changing structure of a network. In this research, an IM method for dynamic networks has been proposed which uses a deep Q-learning (DQL) approach. To learn dynamic features from the network and retain previously learned information, incremental and transfer learning methods have been applied. Experiments substantiate the good performance of the DQL methods and their superiority over compared methods on larger sizes of tested synthetic and real-world networks. These experiments illustrate better performance for incremental and transfer learning methods on real-world networks.

2 - Online Learning Linear Programming Heuristic for Weakly Coupled MDP

Alexandre Reiffers

In this talk, we present novel algorithms for online learning of linear programming heuristics for weakly coupled Markov Decision Processes (MDPs). Leveraging two-timescale stochastic approximation theory, we design simple and efficient algorithms with theoretical guarantees. Furthermore, we show that we can extend our approach to learn policies for continuous state space weakly coupled MDPs, while also demonstrating that certain theoretical guarantees are preserved. Finally, we demonstrate the efficiency of our algorithms on real-world applications, including load-balancing coupled with autoscaling in parallel queues, and monitoring strategy of slowly varying signals in networks.

3 - Algorithms to solve Risk Sensitive MDPs, Games and Applications

Veeraruna Kavitha, Vartika Singh, Tushar Walunj

There are no computationally feasible algorithms that provide solutions to the finite horizon Risk-sensitive Constrained Markov Decision Process (CMDP) problem, even for the problems with moderate horizon. With an aim to design the same, we derive a fixed-point equation such that the optimal policy of the CMDP is also a solution. We further provide two optimization problems equivalent to the CMDP. These formulations are instrumental in designing a global algorithm that converges to the optimal policy. The proposed algorithm is based on random restarts and a local improvement step. Here the local improvement step involves solving a Linear program, and utilizes the solution of the derived fixed-point equation, while, the random restarts ensure global optimization. Such MDPs are utilized to model and derive robust inventory control.

Further, one may have constrained stochastic games whose objective and constraints are a combination of linear and risk-sensitive utilities. The best response becomes a constrained MDP with a combination of linear and risk-sensitive utilities. We build upon the theory developed for constrained risk-sensitive MDP and develop a solution technique

to numerically solve such combined constrained MDPs and eventually the game.

Finally, we suggest an online learning algorithm that can potentially learn the optimal policy, when the data defining the MDP is not known.

4 - Learning Whittle and LP indices in Average-Reward Restless Multi-Armed Bandits

Konstantin Avrachenkov

Restless Multi-Armed Bandits (RMABs) are extensively used in scheduling, resource allocation, marketing and clinical trials, just to name a few application areas. RMABs are Markov Decision Processes with two actions (active and passive modes) for each arm and with a constraint on the number of active arms per time slot. Since in general RMABs are PSPACE-complete, several heuristics such as Whittle index and LP index have been proposed. In this talk, I present reinforcement learning schemes for both Whittle and LP indices with almost sure convergence guarantee in the tabular setting and an empirically efficient Deep Q-learning variants. Several examples, including scheduling in queueing systems, will be presented. This talk is based on joint works with V.S. Borkar and P. Shah from IIT Bombay.

1 - Constraint qualifications and strong global convergence properties of an augmented Lagrangian method on Riemannian manifolds

Orizon P Ferreira, Roberto Andreani, Kelvin Couto, Gabriel Haeser

In the past years, augmented Lagrangian methods have been successfully applied to several classes of non-convex optimization problems, inspiring new developments in both theory and practice. In this paper we bring most of these recent developments from nonlinear programming to the context of optimization on Riemannian manifolds, including equality and inequality constraints. Many research have been conducted on optimization problems on manifolds, however only recently the treatment of the constrained case has been considered. In this paper we propose to bridge this gap with respect to the most recent developments in nonlinear programming. In particular, we formulate several well known constraint qualifications from the Euclidean context which are sufficient for guaranteeing global convergence of augmented Lagrangian methods, without requiring boundedness of the set of Lagrange multipliers. Convergence of the dual sequence can also be assured under a weak constraint qualification. The theory presented is based on so-called sequential optimality conditions, which is a powerful tool used in this context. The paper can also be read with the Euclidean context in mind, serving as a review of the most relevant constraint qualifications and global convergence theory of state-of-the-art augmented Lagrangian methods for nonlinear programming.

2 - On projection mappings and the gradient projection method on hyperbolic space forms

Sandor Zoltan Nemeth, Orizon P Ferreira, Jinzhen Zhu

This talk examines the gradient projection method as a solution approach for constrained optimization problems in kappa-hyperbolic space forms, particularly for potentially non-convex objective functions. We consider both constant and backtracking step sizes in our analysis. Our studies are based on the hyperboloid model, commonly

referred to as the Lorentz model. In our investigation, we present several innovative properties of the intrinsic kappa-projection into convex sets of kappa-hyperbolic space forms. These properties are crucial for analyzing the method and also hold independent significance. We discuss the relationship between the intrinsic kappa-projection and the Euclidean orthogonal projection as well as the Lorentz projection. Moreover, we provide formulas for the intrinsic kappa-projection into specific convex sets using the Euclidean orthogonal projection and the Lorentz projection. Regarding the convergence results of the gradient projection method, we establish two main findings. Firstly, we demonstrate that every accumulation point of the sequence generated by the method with backtracking step sizes is a stationary point for the given problem. Secondly, assuming the Lipschitz continuity of the gradient of the objective function, we show that each accumulation point of the sequence generated by the gradient projection method with a constant step size is also a stationary point. Additionally, we provide an iteration complexity bound.

3 - The Riemannian Convex Bundle Method

Hajg Jasa, Ronny Bergmann, Roland Herzog

Within the context of optimization on manifolds, a research direction of particular interest is the investigation of algorithms fit to optimize non-smooth objectives. This research area is relevant since the need for optimizing non-smooth objective functions arises in many real-world problems and applications such as image and signal restoration, denoising, inpainting, etc. In this talk, we introduce the convex bundle method to solve convex, nonsmooth optimization problems on Riemannian manifolds. Each step of our method is based on a model that involves the convex hull of previously collected subgradients, parallelly transported into the current serious iterate. This approach generalizes the dual form of classical bundle subproblems in Euclidean space. Several numerical examples implemented using the Julia package *Manopt.jl* illustrate the performance of the proposed method and compare it to other non-smooth optimization algorithms.

Variational Methods in Vector Optimization

Stream: Variational Analysis and Continuous Optimization

Invited session

Chair: *Fernando García Castaño*

Chair: *Marco A. López-Cerdá*

1 - Strongly convex sets with variable radii

Florent Nacry

This talk is devoted to the new class of strongly convex sets with variable radii in Hilbert spaces recently introduced by L. Thibault and the author. Such a strong convexity property can be seen as the convex counterpart of the famous phi-convexity introduced by A. Canino in 1988 and thoroughly developed in a 2010 survey by G. Colombo and L. Thibault under the name prox-regularity with variable thickness (also known in the case of constant radius/thickness as proximally smooth sets, positively reached sets, weakly convex sets, $O(2)$ -convex sets, etc.).

Roughly speaking, a strongly convex set with a variable radius (is obviously convex and) has its curvature locally bounded from below by an appropriate function. Whenever the latter function is constant, our strong convexity coincides with the usual strong convexity of sets (see, e.g., a recent survey by V.V. Goncharov and G.E. Ivanov). Strongly convex sets have been involved in various mathematics, including: separation properties, minimal time problem, preservation of prox-regularity, linear differential games, sweeping processes, etc.

The main aim of the presentation is to provide numerous properties and characterizations of strongly convex sets with variable radii through

the differentiability of the so-called farthest distance function, the Lipschitz behavior of the farthest point mapping and the strong monotonicity of truncated normals. Perspectives and open questions would be also provided.

2 - Scalarizations obtained through a property of separation of cones

Fernando García Castaño, Miguel Angel Melguizo Padial, Giovanni Parzanese

In this presentation, we will demonstrate that, given a separation property of cones, a \mathcal{Q} -minimal point in a normed space is the minimum of a specific sublinear function. This observation provides sufficient conditions, via scalarization, for several types of proper efficient points. Furthermore, we will explore necessary and sufficient conditions for approximate Benson and Henig proper efficient points expressed in terms of scalarization. The separation property we consider is a variant of a previously introduced property that had been applied in the setting of reflexive Banach spaces.

3 - Some New Henig-type Existence and Density Results in Non-Convex Vector Optimization Problems

Miguel Angel Melguizo Padial, Fernando García Castaño

In this talk we present sufficient conditions for a set and the ordering cone of a space to ensure the density of the set of Henig proper efficient points in the efficient line. Our results are established in the context of arbitrary normed spaces and are free of convexity assumptions. We extend some previous results established under more restrictive conditions.

4 - Measuring the stability. A paradigmatic problem in optimization

Marco A. López-Cerdá

In this talk we focus mainly on linear programming problems, and particularly on Lipschitz-type properties of the feasible set mapping, the optimal value function, and the optimal set (argmin) mapping. Roughly speaking, we aim to compute or estimate the rate of variation of feasible/optimal solutions with respect to the problem's data perturbations. Some of these properties are local (as Aubin property and calmness), as far as they concentrate around a certain solution nearby a given parameter. Some other properties (such as Hoffman stability) are of a global nature, since they tackle global variations of the whole solution set. We emphasize the fact that the quantitative stability measures provided in this talk are mainly point-based; thus they are conceptually implementable in practice.

it is the availability of supply or the increasing demand that drives sustainability transient consumption is often discussed in economic circles. From the complex systems perspective, it is their interaction that matters. This article explores how consumer preferences and restaurant menus co-evolve to contribute to a more sustainable food system and how this co-evolution is affected by different policy instruments. We use a spatially explicit agent-based model of the catering industry in Amsterdam as a case study. The model is built using spatial microsimulation to expand on survey data from a discrete choice experiment about restaurants in Amsterdam. We observe that in the absence of policy interventions, it takes quite a lot of time for changes in diet patterns to occur. Multiple cities are working on their sustainability. Based on the generated insights, we expect our research to contribute to the current debate on the policy interventions to achieve sustainable urban food systems and the SDGs, and to be of consequence across multiple cities worldwide.

2 - Unveiling Behavioral Heterogeneity: An Agent-Based Model Exploration of Farmer Decision-Making in the Face of Climate Change

Paolo Gazzotti, Sandra Ricart, Andrea Castelletti

In the face of climate change threats to agriculture, understanding farmers' decisions on crop selection and irrigation practices becomes crucial, as they tend to be significantly shaped by risk preferences. Farmers, who all recognize shifts like increased drought severity, exhibit diverse reactions influenced by individual risk aversion, satisfaction, uncertainty, and peer comparisons. Agent-based modeling (ABM) stands out as an essential tool for capturing system dynamics and simulating farmers-environment-climate interactions. Despite calls for realistic human behavior integration, the prevailing paradigm still favors rational agents. Here we present an ABM application in Italy's Adda River basin, modeling farmers' decisions on crops and irrigation methods. To understand the system's response and resilience to changing climates, we implemented diverse behavioral sub-models. The first maximizes profit with classic perfect foresight. The second introduces climate uncertainty and risk aversion variations based on farmers' memory. The third, a comprehensive behavioral model, considers reference points and loss aversion, acknowledging decisions beyond profit. It offers a holistic view of farmers' choices amid uncertainty and risk, calibrated with collected survey data. Preliminary findings uncover significant differences in system dynamics and resilience across the behavioral setups, providing insights into their efficacy and suitability.

3 - Resilient national cold chain deployment for addressing food waste and achieving economic prosperity in the Global South: An agent-based approach

Adam Gripton, Aghdas Badiee, Phil Greening

Many Global South countries currently suffer from high degrees of agricultural food waste due to the warm climate and lack of an integrated national cold chain supply network. This can lead to many societal issues that hinder growth and development, including poor outcomes for population health and nutrition metrics, a "poverty trap" for smallholder farmers without market options for selling their produce, and for the national economy through lack of cold-chain traceability that would allow access to more lucrative export markets. Design of a national cold-chain network as critical infrastructure requires consideration of a wide range of market forces and behaviours in such a tightly-coupled system, as well as dealing with the inherent uncertainty in such interactions, to ensure that placement and operation of cold staging facilities can be optimally planned to achieve the desired national outcomes for public health and economic wealth. Agent-based modelling (ABM) can assist in capturing these phenomena to allow a future scenario of cold-chain infrastructure deployment to be tested for efficiency and resilience in the face of uncertainty and black-swan events such as extreme weather events caused by climate change. We present preliminary results, applied to Rwanda as a case study, of a bespoke ABM solution designed to show the effects of offering cold chain as an alternative business model to farmers and showing how network placement affects national outcomes.

1 - Mapping Energy Poverty: A Multi-Criteria Classification Framework for the European Union

José Rui Figueira, Madalena Alexandre Lourenço, Carla Henriques, Miguel Pereira, Carlos Santos Silva

Energy poverty stands as a pressing issue across the European Union (EU), casting shadows over public health and hindering sustainable development efforts. Despite its prominence, scholarly literature reveals a dearth of studies quantifying the breadth of fuel poverty within the EU. Remarkably, none have ventured into applying methods from the ELECTRE family. In response to this research gap, our study undertakes the task of classifying energy poverty across EU member states in the year 2020 by employing the innovative ELECTRE-Tri-nC method. To further refine our analysis, we supplement this method with the Simos-Roy-Figueira (SRF) method, aiding in the assignment of weights to our selected criteria. Our model integrates nine distinct criteria to discern the energy poverty levels of 24 EU member states. Unveiling the findings of our comprehensive study, we observe a distinct trend: Eastern and Southern Europe grapple with elevated levels of energy poverty, while the Scandinavian nations and Central Europe demonstrate commendable low levels. Meanwhile, Western Europe and the Baltic countries fall within the moderate spectrum of energy poverty. By shedding light on these disparities, our study not only underscores the urgency of addressing energy poverty but also highlights regional variations that demand tailored interventions and policy considerations. In doing so, we endeavour to catalyse informed discourse and strategic action aimed at alleviating the burdens of energy pove

2 - A Comprehensive Model for Supply Chain Resilience Measuring

Chien-Wen Chen, Ching-Torng Lin

Business globalization and strategic sourcing have made supply chain networks become length and complex, which have increased it more vulnerable and uncertain to disruptions. Geographical wars, such as the Russia-Ukraine war, have shown the disruptive effect of these catastrophes, which inspires me to think that traditional supply chain management fails to cope with such disruption challenges. To address these current and potentially future challenges, scholars and practitioners suggested that supply chain management must incorporate resilience, robustness, and risk management capability. There are several approaches to assessing a resilient supply chain. Due to the ambiguity of resilience assessment, most measures are described subjectively using linguistic terms. Abandon the traditional way of assessing resilience, this paper develops a Fuzzy Resilience Index in Supply Chain (FRISC) to measure the level of supply chain resilience. The FRISC comprises attribute ratings and corresponding weights and is aggregated by a fuzzy weighted average. Finally, an example is presented at the end of the paper to illustrate the procedure of the proposed method. The results show that the proposed model can provide more meaningful results to the analyst and can efficiently assist managers in dealing with both ambiguity and complexity in supply chain resilience auditing.

3 - Unveiling Success in Supply Chain Digital Transformation: A Comprehensive Analysis of Critical Factors for Resilience and Sustainability in Indian Manufacturing

Jeetu Rana, Yash Daultani, Mohit Goswami, Sushil Kumar

This study delves into the emerging field of Supply Chain Digital Transformation (SCDT) with a specific focus on fostering resilience and sustainability within the Indian manufacturing context. Identifying and analyzing the Critical Success Factors (CSFs) underpinning

SCDT success is the central theme. Through an extensive literature review and collaboration with industry experts, fourteen CSFs were pinpointed. The study employs a unique approach — Grey Causal Modelling, to unravel the interdependencies and relative importance of these factors. Two pivotal cause factors, "Vision for Digital Operations" and "Coordination and Collaboration," emerged as crucial in driving SCDT success. By prioritizing these factors, manufacturing firms can enhance their chances of achieving successful SCDT with resilience and sustainability objectives. The research not only contributes valuable insights for organizations navigating the digital landscape but also sheds light on the intricacies of SCDT in the dynamic environment of Indian manufacturing. The study underscores the strategic importance of identifying and nurturing specific factors, offering guidance for firms aiming to thrive in today's digitally-driven world.

4 - Addressing Challenges in Multicriteria Decision-Making: Introducing the Method and User-Friendly Software Called VIKOR-HS

Renata Pelissari, Rafaela Heloisa Carvalho Machado, Bernardo Reis, Artur Almeida Santos, Samuel Vieira Conceição

Complex decision-making problems often have specific configurations such as the need to organize criteria hierarchically and the difficulty in setting importance weights to these criteria. These challenges have not been fully addressed yet when it comes to the multicriteria decision-making method VIKOR. Our first proposal is to introduce the VIKOR-HS method to bridge this gap. This method integrates a variant of the Multiple Criteria Hierarchy Process (MCHP) into VIKOR, facilitating consideration of multiple levels for decision criteria, and incorporates the Stochastic Multicriteria Acceptability Analysis (SMAA) for eliciting criteria weights across various hierarchy levels. Despite this contribution, a challenge that remains concerns the difficulty in applying such a method in real-life decision-making scenarios due to its demand for mathematical and programming knowledge that is often incompatible with that possessed by typical users. Our second contribution addresses this concern by proposing a user-friendly software tailored for implementing the VIKOR-HS method. To demonstrate the efficacy of the VIKOR-HS method and accompanying software, we applied it to assess the sustainability of different animal production alternatives in Brazil, a problem previously explored in the literature. Notably, the software facilitates robustness evaluation for each alternative while substantially reducing the complexity associated with employing a robust multicriteria approach.

5 - Evaluation of Sustainable Performance Based on Linguistic Entropy and TOPSIS Methods

Chen-Tung Chen, Ke-Fang Chen

In recent years, sustainable development has become a core issue in enterprise management and value creation. In order to ensure the performance of the implementation of the sustainable development goals, the enterprise must evaluate sustainable performance appropriately. Due to the characteristics of high uncertainty and high complexity, it is an important issue to apply fuzzy sets theory with multiple experts to construct a sustainable performance evaluation model. It can be regarded as a group multiple-criteria decision-making problem. The opinions of experts always are fuzziness and uncertainty, it is reasonable for experts to use the linguistic variables to express their subjective opinions in the evaluation process. In addition, the TOPSIS (Technique for Order Preference by Similarity to an Ideal Solution) is one of famous methods to deal with the decision-making problems. Therefore, this paper will combine entropy method with TOPSIS based on linguistic variables to construct a systematic evaluation model of sustainable performance. And then, this paper will propose a linguistic entropy TOPSIS algorithm (LE-TOPSIS), which will use entropy method to calculate the weights of criteria and to determine the ranking order of all enterprises by using TOPSIS. Finally, an example will present in accordance with the LE-TOPSIS algorithm to illustrate the effectiveness of the proposed method.

Artificial Intelligence and Machine Learning for Decision Support

Stream: Decision Support Systems

Invited session

Chair: Stefan Minner

1 - Conversational Decision Support Systems: a telling-to-modeling AI-enhanced approach

Mariusz Kaleta

In the full cycle of the Operations Research methodology, artificial intelligence is most prominently utilized in the algorithmic aspect. Meanwhile, modeling is traditionally considered an art exclusive to human being experts. What if we could simply tell the computer the problem and, in return, receive an optimization model and its solution? We propose a new class of Decision Support Systems (DSS), termed Conversational Decision Support Systems (C-DSS). These systems, empowered by agents based on large language models, perform the art of modeling and elevate human-machine interaction to the interface of problem definition and mathematical modeling, using natural language as the primary mode of communication. In our concept, a decision-maker interacts with the C-DSS by discussing the problem to obtain decision proposals.

First, we analyze how general-purpose language models handle problems that can be modeled as mixed-integer problems, requiring various modeling techniques such as linearization of convex/concave functions, logical conditions, and indicator constraints, among others. Additionally, we enhance the general-purpose language model with specialized knowledge using the Retrieval Augmented Generation method. The generated mathematical programming models require verification, which can also be facilitated by another language model-based agent. Therefore, we propose an architecture of C-DSS powered by several specialized language model-based agents.

2 - Forecasting B2B markets with machine learning and predator-prey models: empirical evidence from global Aerospace companies

Dina Litsiou, Chaitanya Kapoor, Konstantinos Nikolopoulos, Chrysovalantis Vasilakis

In this world of such a volatile, uncertain, and changing environment and markets, especially in a post-pandemic 'new-normal' context, it is very important to be ahead of competitors so as to maintain one's market share. This is true for all markets, but more than anything for B2B markets that are affected immediately from supply chain disruptions and need to employ multiple channels to survive and thrive in turbulent times. Products and services can be sold profitably only if customer needs are satisfied at acceptable (low-ish) prices. Many factors are involved in making a product cost efficient, one of which is forecasting. Forecasting is one of the most essential parts of almost every supply chain in the world. This paper contributes towards the improvements in the forecasting methods currently being used by forecasters in B2B markets, a key area in the early days of Industrial Marketing Management (70s and 80s) that has been revived recently due to the revolution of big data predictive and prescriptive analytics. This paper is focused on forecasting the competing product life cycles using Lotka-Volterra predator-prey equations. The objective of this paper is to find a better version of Lotka-Volterra equations suited for general market products. Various regression analysis techniques have been applied in order to make an attempt to find the best way of forecasting using Lotka-Volterra equations.

3 - Multi Agent Reinforcement Learning and Graph Neural Networks for Inventory Management

Niki Kotecha, Antonio del Rio Chanona

Current supply chains operate under uncertain environments causing risks in disruptions and sub-optimal performance due to operational failure or lack of coordination. The inventory control problem, a sequential decision-making problem, is challenged by stochastic and volatile factors such as lead times and seasonal demand patterns, often resulting in sub-optimal performance. Reinforcement learning (RL) remains a promising alternative to enhance decision-making in supply chains. However, as the supply chain grows in size, the complexity of decision-making can grow significantly which may hinder the performance of traditional RL algorithms as they struggle to scale efficiently. The extension of single-agent RL to multi-agent RL allows for scalability as well as a decentralised decision-making framework of individual entities. Our methodology leverages on the inherent graph structure of a supply chain, developing a multi agent RL framework with Graph Neural Networks for a multi-echelon multi-product inventory management system. We show the benefits of a collaborative approach by testing the policies on a series of disruptions. Additionally, the framework moves computational costs from online to offline, ensuring faster decision making than most efficient optimisation methods. As a result, the methodology proposed shows promising scalability with number of agents for a decentralised and online decision-making framework whilst still ensuring collaboration between entities.

4 - Understand Your Decision Rather than Your Model: Towards Explainable Deep Learning Approaches for Sustainable Commodity Procurement

Moritz Rettinger, Stefan Minner

Hedging against price increases is particularly important in times of significant market uncertainty and price volatility. For commodity procuring firms, futures contracts are a widespread means of financially hedging price risks. Recently, data-driven decision-support approaches have been developed, with deep learning-based methods achieving particularly good results in capturing non-linear relationships between external features and price trends. We employ a prescriptive deep-learning approach modeling hedging decisions as a multi-label time series classification problem. We backtest the performance in two evaluation periods for natural gas, crude oil, nickel, and copper. The approach performs well in the evaluation period of the testing framework (2018-2020) yet fails to capture the market disruptions (pandemic, geopolitical developments) in the second evaluation period (2021-2023), yielding significant hedging losses or degenerating into a simple hand-to-mouth procurement policy. We employ explainable artificial intelligence to analyze the performance for both periods. The results show that the models fail to perform well under market regime switches and disruptive events within the considered feature set.

1 - A Multicriteria Approach for the Definition of Priorities of Intervention for Roadway Bridges and Viaducts

Chiara D'Alpaos, Flora Faleschini, Silvia Manarin, Carlo Pellegrino, Mariano Angelo Zanini

In recent years, the assessment of structural performances and functionality of roadway bridges and viaducts has become a key issue in Italy and in most European Countries. Large part of the existing stock exhibits deficiencies due to the aging of the structures and the ever-growing demanding traffic conditions and safety requirements, compared to the original design phase. In 2020, in Italy were issued to assess bridges and viaducts risk exposure and proposed a multilevel approach based on census, visual inspection, and a preliminary and qualitative risk indicator. To define this risk indicator, four types of risks are considered: structural and foundation risk, seismic risk, landslide risk, and hydraulic risk. After this preliminary evaluation, in-depth tests and more accurate analyses should be implemented on any bridge or viaduct exposed to high risk. During the first application of these guidelines, several difficulties were detected in finalizing a ranking of the infrastructures included in the same class of risk. This paper proposes an AHP absolute model to rank roadway bridges and viaducts by priority on intervention, based on structural and foundation risks. In detail, to identify criteria, sub-criteria, and rating, and define the hierarchy, an extensive literature review was conducted and a pool of experts was interviewed via a Delphi survey process. Focus groups were organized to validate the hierarchy by dynamic discussion and identify local and global priorities.

2 - Argumentation Schemes for Urban Decision Support

Isabella Lami, Marta Bottero, Beatrice Mecca, Gabriella Pigozzi, Alexis Tsoukias

The decision-making process in urban planning and design projects is inherently complex as it embraces so many different actors, interests, dimensions and uncertainties. Evaluation plays a key role in supporting such processes, as a guide to prioritising decisions based on the observation of data derived from analyses, measurements and estimations. In this context, the paper investigates the potential benefits of argumentation theory aimed at managing the complexity of information and knowledge about the situation under analysis through specific schemes. Indeed, argumentation-based approaches make it possible not only to identify a 'good' choice, but also to formulate, through a logic-based formalism, a final recommendation in a graphic and mutually comprehensible form. In this sense, the paper starts from the exploration of an emblematic case study of the city of Turin, which saw numerous actors, interests and critical points in its decision-making process, proposing an a posteriori argumentation scheme. The latter highlights the points of agreement and disagreement that led to a design strategy that was justified and satisfactory to the decision-making actors. Through application, the potential and criticalities of this approach in decision support in the urban context are observed.

3 - The role of Multi Criteria Evaluation Tools to implement the Circular City Model

Mariarosaria Angrisano, Marta Bottero, Giulio Cavana, Antonia Gravagnuolo, Luigi Fusco Girard, Francesco Fabbrocino

The challenges of sustainable development are mainly concentrated in urban areas. Consequently, cities are key places for the implementation of strategies and initiatives to achieve Sustainable Development Goals. The implementation of circular cities produces multidimensional benefits in the environmental, economic, social and cultural dimensions. The circular city requires the activation of integrated and multidimensional urban development policies, capable to involve different disciplines and sectors. The circular city model implementation necessarily requires integrated evaluation tools (multicriteria, multi-group and quanti-qualitative) able to capture the multidimensional impacts that it is able to produce and considering all the subjects/actors involved in its implementation. Within the Italian research project PRIN "TReE - Supporting the Transition to Ecological Economy in Italian cities Regeneration: circular model tools for reusing architecture and infrastructures" an evaluation framework will be tested to define alternatives for the reuse of cultural heritage in line with the circular city model. The objective is the creation of a new Multicriteria Evaluation Framework, based on the integration of different existing methods, to respond to the need to analyze and evaluate the multidimensional impacts generated by adaptive reuse interventions of cultural heritage, under the paradigm of circular and sustainable economy and social innovation.

4 - A Compromise Programming Approach for Assessing the Biophysical Suitability of the Territory: The Case of the Loulé Municipality

António Xavier, Maria de Belém Costa Freitas, Carla Antunes

Land use fragmentation is an important issue for management and rural development. For the last few decades, the relationship between mankind and land has become more dynamic though the traditional cadastral system has been slow in responding to the changing needs of the society. Generally defined, land-use suitability analysis aims at identifying the most appropriate spatial pattern for future land uses respecting specific requirements and preferences in what concerns the activities developed. The analysis of the land use suitability implies not only to consider the best aggregate solution, but also the balance among the different criteria, which calls for the necessity of multicriteria decision analysis techniques. This article proposes a compromise programming approach for determining the biophysical potential of land parcels. The approach has 4 steps: 1) Cluster analysis do identify homogeneous zones within the study area; 2) Compromise programming approach for the suitability index building and ranking construction; 3) Statistical analysis (statistical tests to assess the differences among clusters); 4) Spatial analysis of the results. The approach was implemented in the Loulé municipality, Portugal, in more than 50000 parcels. Results were promising since the approach was able to create a ranking of parcels that have different biophysical conditions, proving that this approach is relevant and interesting for land management.

DEA applications in Environment and Sustainability I

Stream: Data Envelopment Analysis and its Application
Invited session

Chair: [Li-Ting Yeh](#)

1 - A cross-efficiency DEA approach for composite indicators: Revisiting Environmental Performance Index

Saransh Tiwari, Sanjeet Singh, Utsav Pandey

To promote and encourage sustainable development in favour of ensuring an egalitarian and environmentally secure future, Yale and Columbia Universities jointly with World Economic Forum developed the Environmental Performance Index (EPI). The EPI is a composite index of environmental and sustainability indicators that quantifies and assesses a country's environmental performance based on three broad policy objectives: climate change, environmental health, and ecosystem vitality. This paper proposes an approach based on the cross-efficiency data envelopment analysis (DEA) for estimating the EPI. We propose cross-efficiency models for settings where there are only outputs (without inputs), as in composite indicator construction, that provides unique cross-efficiency scores. As cross-efficiency incorporates both self- and peer-evaluation, it offers a more acceptable and reasonable mechanism for computing the EPI. Utilizing the scores obtained via the cross-efficiency DEA approach, we extend our analysis by employing the regression to determine the relative importance and contribution of the variables used in EPI construction and find suitable weights that could be assigned to the indicators if the decision-maker desires to estimate the countries' EPI scores via fixed weights. The limitations of the existing methodology for EPI estimation, which is based on a non-optimization approach with weights assigned to the indicators subjectively, are overcome in our proposed approach.

2 - An Analysis of the Efficiency of European Funds in Sustainable Development in Portugal

Sérgio Barreto, Daniel Colares, Gilberto Fernandes

Assessing the impact that European Funds have on people's lives is an area that has received the attention of researchers and institutions. On the one hand, citizens demand better results and more information, on the other hand, institutions need methodologies that allow them to measure the impact of investments. Considering an investment horizon of 14 years (between 2007 and 2020) and a development assessment period of 7 years (between 2014 and 2020), this research uses a DEA methodology to evaluate how the 308 Portuguese municipalities use financial and human resources (inputs) to achieve sustainable development (output). As a result, each municipality is characterized by a CCR efficiency measure, being positioned towards the efficient frontier. In this way, it is possible to identify municipalities with best practices and the effort required from the rest to achieve them. Graphic maps facilitate the communication of information by illustrating the distribution of efficiency throughout the territory.

3 - Extending Eco-Efficiency Evaluation in DEA through a Lens of Strong Sustainability

Xun Zhou

Nonparametric efficiency analysis methods such as data envelopment analysis (DEA) have been widely employed for evaluating eco-efficiency. However, virtually all published studies in this literature implicitly assume weak sustainability. This is a very strong assumption that allows for substitution among different forms of inputs and/or outputs, treating ecological conservation as merely one among several competing objectives that can be traded off against economic growth. To broaden the scope of nonparametric eco-efficiency evaluation, this paper proposes a novel approach based on a strong sustainability perspective. Drawing on a newly introduced method termed Fixed Proportion Constrained DEA, our eco-efficiency evaluation approach restricts the substitutability among inputs and/or transformability among outputs, highlighting the intrinsic value and irreplaceability of ecosystem services and natural capital. By incorporating this perspective into eco-efficiency measurement, our proposed method offers a more comprehensive understanding of sustainability and underscores the importance of preserving natural ecosystems for future generations.

4 - Water Resource Reallocation Planning with Integrated Hydroelectric Reservoirs in Taiwan: Constructing a Centralized Data Envelopment Analysis Model with Non-separable

Li-Ting Yeh

The uneven allocation of water resources leads to hydropower instability. Therefore, Taiwanese policy-makers must find ways to more effectively reallocate water resources among hydroelectric reservoirs.

Since hydroelectric reservoirs are managed by the centralized administration, Taiwanese policy-makers can pursue the overall performance of all hydroelectric reservoirs. Conventional centralized data envelopment analysis (DEA) models focus on the reallocation of each resource input based on the expansion of total outputs. However, these centralized models rarely consider that some resource inputs are closely related to certain outputs. To bridge this gap, this paper presents a centralized DEA model with non-separable. The proposed models aim to address the planning for reallocating water resources among hydroelectric reservoirs in Taiwan.

Lot-sizing with energy aspects

Stream: Lot Sizing, Lot Scheduling and Production Planning

Invited session

Chair: *Onur Kilic*

1 - Energy Requirements Planning Problem

Mehmet Onal, Ihsan Yanikoglu

We consider the energy planning problem of a heating plant that serves to heat a set of houses (flats). Each flat served by the plant has certain temperature requirements throughout the day. These flats are heated by radiators that are fed by hot water distributed from and heated in the heating plant. The plant can remotely control hot water flow rates through these radiators. For each flat the plant can choose among a discrete set of flow rates. The plant can create energy by running three different boilers with different capacities and running costs. The problem is to create an energy plan with minimum cost to satisfy temperature requirements of flats. We analyze the problem within the context of economic lot sizing problem and present solution approaches to some special cases.

2 - A multi-stage stochastic programming model for lot-sizing with onsite generation of renewable energy

Ruiwen Liao, Franco Quezada, Céline Gicquel, Safia Kedad-Sidhoum

One way to achieve energy efficiency in manufacturing is to equip plants with on-site renewable energy generation system to partially power industrial processes. However, renewable energy sources are intermittent and the availability is difficult to predict accurately. Therefore, we study an integrated industrial production planning and energy supply problem under uncertain renewable energy availability. We propose a multi-stage stochastic programming model for this problem. The planning horizon is divided into multiple stages according to the time at which the PV availability information is updated. The intermittency of PV generation is represented by a scenario tree. The resulting production and energy supply planning can be seen as a multi-stage decision process where some decisions are made at the beginning of the planning horizon whereas the others are postponed to later decision stages when more information on the uncertain parameters are revealed. At the beginning of the planning horizon, we build a production plan for a proportional lot-sizing and scheduling problem in a single-machine multi-item setting. Then based on the available information on PV generation, an energy supply plan is constructed for the upcoming stage, which has to satisfy the energy demand of the system which has been previously determined by the production plan at the beginning of the planning horizon. Computational experiments will be presented to show the practical efficiency of the proposed approach.

3 - Comparison of Discrete Time and Precedence Based MILP Formulations of Production Scheduling for Furniture Manufacturing

Károly Kalauz, Botond Bertok, Marton Frits

Effective production scheduling is essential for optimizing productivity and meeting demand within dynamic production systems. This study conducts a comparative analysis of two modeling techniques, Process Network Synthesis (PNS) and Time-Constrained Process Network Synthesis (TCPNS), in the context of mass production. Both techniques, rooted in P-graphs, excellent in managing complex and flexible recipes. The precedence-based resource scheduling model employing TCPNS, provides high precision in schedule generation and effective handling of complex changeover times. However, the required computational effort may exceed practical limitations. In contrast, the discrete time process flow model using PNS offers a fast computation through time discretization and a series of combinatorial techniques to reduce the complexity of the mathematical model of the initial problem and sub-problems. In addition to the comparative analysis, this study examines algorithmic model generation for both precedence and discrete-time formulation, with multiple resolutions in the latter case. This nuanced approach provides an enhanced understanding of the practical applicability and computational efficiency of PNS and TCPNS methodologies, particularly in real-life furniture manufacturing scenarios.

4 - Dynamic lot-sizing for LNG inventories

Onur Kilic

We consider a lot-sizing problem motivated by liquefied natural gas (LNG). LNG is an alternative transportation fuel. It can be supplied from alternative sources with different quality and price, at different costs. LNG is subject to quality deterioration. It is yet possible to upgrade its quality by mixing different loads with different levels of quality. LNG is provided to customers via special-purpose facilities. We address the lot-sizing problem in such a facility. The problem entails finding a minimum-cost replenishment plan satisfying demands over a finite planning horizon, while meeting a minimum quality level. We initially formulate the problem as a mixed integer non-linear program, which we then linearize by means of standard linearization techniques. This model, however, is computationally too expensive to be used in practice. To overcome the computational challenge, we identify a class of feasible solutions and develop an efficient mixed-integer linear program by which we can find a minimum-cost solution within this specified class of solutions. We numerically illustrate that our approach provides optimal or close-to-optimal solutions for practical instances within very reasonable computational times.

Tuesday, 10:30-12:00 - Room: M2 (building: 101)

Retail Operations and Marketing

Stream: Retail Operations

Invited session

Chair: *Winfried Steiner*

Chair: *Pnina Feldman*

1 - Impact of consumers' environmental awareness on inventory decisions for a retailer in the textile industry

Martin Waitz, Lena Silbermayr, Danja Sonntag

Textile waste is a crucial problem for today's society. The majority of it is generated by the consumer and does not end up as separate waste, but is mixed with residual waste and then burned for energy recovery. To obtain recycled textiles, the operational processes required (e.g., collection and sorting) are still costly compared to using virgin materials, resulting in higher production costs for greener products. The increase in recycled materials for textiles therefore depends on consumers' willingness to pay a premium for more environmentally friendly products. While some customers may be willing to pay such a premium, others may focus solely on the price of a textile. Understanding these customer segments, particularly a customer's individual willingness to pay for a greener product, will benefit a retailer that offers multiple substitutable products when making inventory decisions. In this work, we

investigate the influence of consumers' environmental awareness when purchasing textiles and its impact on inventory decisions of a retailer. Therefore, an empirical study including a choice-based conjoint analysis is carried out to reveal consumers' preferences and willingness-to-pay for 'greener' textiles in Austria. These empirical findings are used by a newsvendor model to derive inventory decisions of a retailer, which are evaluated both economically and ecologically.

2 - Dynamic effects of store promotions on conversion fraction: Expanding technology applications with innovative analytics

Leonardo Epstein, Ignacio Inostroza-Quezada

In retail settings conversion fractions (CFs) matter to managers because they measure the stores' effectiveness to convert visitors into buyers. Despite CFs importance, available methods to evaluate effects of a given marketing action (MA) on CF are scarce and provide limited evaluations of these effects. We present an approach that (i) builds a model for conversion probabilities with data outside the MA period, (ii) uses this model to predict a baseline for conversion probabilities during the promotional period conditional on the counterfactual hypothesis that the MA had not occurred, and (iii) evaluates MA effects on CF by comparing this baseline to observed data during the MA period. We illustrate our approach with data from an actual MA consisting on a two-day promotion. The analysis combines arrival data from video images and conversion data from cash registers.

3 - Decision support for product diffusion in retail - The impact of geospatial and temporal access.

Florian Cramer, Christian Fikar

Despite the increasing recognition of local actors as pivotal agents for sustainability in food chains, numerous innovative products, particularly from startups, encounter difficulties in reaching consumers. Offering such products can facilitate consumer interest and position retailers as enablers of sustainable food systems. However, listing a new product can not only bring competitive advantages but also lead to risks, e.g., due to potential losses if the product is rejected. Retailers often have to rely on intuition and estimate a product's potential due to unknown rejection probabilities. This research delves into the early stages of product diffusion by examining the effectiveness of traditional stationary brick-and-mortar stores in contrast to the agility of mobile pop-up stores. Utilizing an agent-based simulation (ABS) model, we replicate the product diffusion process and employ a regression model to determine promising store locations. Through our investigation, we unveil how combining ABS and machine learning procedures can provide decision support for both retailers and MSMEs. For a limited number of stores, introducing a single mobile store can considerably expedite product diffusion. Generally, using mobile stores can enable a more pronounced market penetration, whereas stationary stores yield higher sales due to recurrent purchases. Furthermore, our findings show how the probability of rejection influences the shape of the product diffusion curve.

4 - The Enigma of Ticket Exchanges (and Other Reselling Markets)

Pnina Feldman

It has long been established in the literature and observed in practice that sellers can benefit from allowing consumers to purchase in advance of the date of consumption. Because of this advance purchasing, consumers can find themselves either with a ticket that they no longer want or without a ticket that they wish to have. In the past, scalpers would facilitate transactions among these consumers for a fee. Sellers historically disliked those practices and actively worked to prevent them. We obtain a stark finding: an unfettered and efficient reselling market eliminates all of the benefits of advance selling, which justifies sellers' historic hostility to reselling. But now ticket exchanges are common, growing, and even embraced by sellers. What changed? We present a theory that demonstrates reselling is actually beneficial for sellers under one crucial condition: the seller must be able to have some control over the reselling process, thereby allowing the seller to earn something from each transaction. The old-fashioned paper ticket did not give such control, but technology now enables electronic tickets, which do. In fact, a seller cannot earn more than what it receives

from a properly designed and efficient reselling market (reselling is an optimal mechanism). And such a market eliminates the opportunities for speculators and can also be beneficial to consumers. In sum, our results explain why the view towards reselling has shifted dramatically.

1 - Joint Optimization of Electric Bus Scheduling and Fast Charging Infrastructure Location Planning

Kayhan Alamatsaz, Frédéric Quesnel

Many transit authorities are switching from diesel buses to electric ones to address concerns over air pollution, greenhouse gas emissions, and the growing demand for energy. While there are many existing scheduling models for diesel buses, they would not fit electric buses (EBs) because EBs have a shorter range and take longer to charge. This has led to new research, including this study, which looks at both how to schedule EBs and where to place fast-charging stations with the objective of minimizing the total system costs. These costs include purchasing and operating of EBs and installing the charging stations. In our research, we developed two types of mathematical models to find the best schedules and charging station locations. We created a Mixed-Integer Linear Programming (MILP) for an arc-based model and an Integer Linear Programming (ILP) model for a path-based model. To solve these models, we employed a Cplex solver and a Branch-and-Price algorithm. After testing these methods with various scenarios, we found that the Branch-and-Price algorithm worked faster than the Cplex solver. Lastly, we did a sensitivity analysis to find out which type of electric bus is most cost-effective, taking into account the actual features of different buses. We also looked at how changes in the buses' battery sizes and travel ranges would affect the optimum solution.

2 - A matheuristic for a multi-day electric bus assignment and recharge scheduling problem

Pierre Vendé, Guy Desaulniers, Michel Gendreau, Yannick Kergosien, Jorge E. Mendoza

To limit greenhouse gas emissions in the public transportation sector, transit authorities are constantly increasing the proportion of electric buses (EBs) in their fleets, creating complex decision problems to charge the vehicles. In order to facilitate the scheduling of all charging operations, it might be efficient to charge EBs both overnight and at long-term stops during the day, to balance the charged quantities. In this study, we consider a multi-day electric bus assignment and recharge scheduling problem which can be defined as follows. Given a set of vehicle blocks (sequences of timetabled bus trips that should be operated by the same bus on a given day), a set of EBs and a set of chargers, the objective is to assign an EB to each block over multiple days and to schedule both overnight and en-route recharging operations. Chargers are installed at the depot, and sufficiently long stops. Each charger has its own charging function represented by a piecewise linear function. The decision are made ensuring that the EBs never run out of energy performing their assigned blocks, the charging capacity at any location should not be exceeded, and the sum of the total charging costs and long run damages on the battery are minimized. We first model this problem as a MILP that can be solved with a commercial solver. Then, to yield faster computational times, we propose an iterative matheuristic based on the MILP.

3 - Charge Scheduling with Renewables for Electric Buses Using Stochastic Optimization

Rito Brata Nath, Madhusudan Baldua, Vivek Vasudeva, Tarun Rambha

While electrification of urban transit systems is underway worldwide, it is essential to integrate it with renewable energy sources to make it fully sustainable. The intermittent nature of renewables poses a challenge in deciding the required solar panels and battery storage capacity at charging locations. To address these challenges, we propose a two-stage stochastic programming model considering uncertainties in solar energy generation and bus energy consumption under dynamic time-of-use electricity prices. Specifically, we formulate the problem as a multi-scenario linear program and employ a Benders' decomposition approach where the first stage (long-term) master variables determine the contracted power grid capacity, battery storage capacity, and the area of solar panels installed at each charging location. The second stage variables (scenario-specific) associated with each child problem prescribe the energy transferred to buses from the grid or solar-based power systems during layovers. We present a case study on the Arlington bus network, US, for 52 scenarios with 3337 trips, where 145 buses and 26 charging locations are required as per a concurrent scheduler algorithm. The solar energy generation data is collected from the National Renewable Energy Laboratory database. Our results reveal that the Benders' decomposition is faster compared to the Simplex algorithm, and the scenario-based schedule adapts better to the uncertainties than the average scenario schedule.

4 - An Analytical Approach to Designing an Efficient Strategy for Scheduling Chargers and Electric Charging Times for a Public Bus Company.

Jaime Miranda, Pablo Chaparro

Amid growing concerns about climate change and the urgency to lower emissions, there's a significant shift towards sustainable public transportation. Electric bus fleets emerge as a pivotal solution to decrease reliance on fossil fuels and reduce greenhouse gas emissions.

This study aims to integrate an electric fleet into a public transit system transitioning from diesel to electric propulsion. The goal is to formulate an efficient charging schedule strategy, optimizing charger and bus usage.

Our methodology involves data collection from a transitioning company, developing an optimization model considering operational constraints like current fleet schedules, charger availability at depots, electric bus range limits, and electrical grid capacity.

Using mixed-integer programming, we aim to create optimal charging schedules and amounts, reducing the need for numerous chargers and daily charging, thereby cutting costs, boosting operational efficiency, extending battery life, and ensuring efficient energy use at depots.

This approach promises significant implications for sustainable transit, showcasing how careful planning and technological solutions can address the logistical challenges of electrifying public transportation fleets.

1 - Cardinality Constraints Meet Large-scale Portfolio

Yuan Chen, Immanuel Bomze, Nikolaus Hautsch, Bo Peng

In financial econometrics, the focus is often on improving covariance matrix estimations rather than addressing optimization problems with constraints for better portfolio management. This paper argues that combining these advanced estimation methods with optimization that includes specific limits, like cardinality constraints, enhances decision-making and investment strategies. Cardinality constraints limit the

number of assets in a portfolio, potentially making simpler estimators like the sample covariance sufficient for investment decisions, especially when dealing with large dimensions that typically introduce significant estimation errors affecting portfolio performance.

We also address the issue of managing portfolios when there are fewer data points than assets, leading to non-invertible, noisy covariance matrices. Cardinality constraints simplify this challenge, making it possible to aim for a global minimum variance portfolio despite these limitations.

Empirically, we find that smaller portfolios, constrained by cardinality to include only a subset of available assets, can achieve diversification similar to market portfolios while reducing transaction costs and simplifying analysis. This suggests focusing on smaller, strategically selected portfolios could offer investors efficient and cost-effective outcomes.

2 - Margin Optimal Trees: a novel formulation and a SVM-based decomposition approach

Marta Monaci, Laura Palagi

In recent years there has been growing attention to interpretable machine learning models which can give explanatory insights into their decision-making process. Thanks to their interpretability, decision trees have been intensively studied for classification tasks. Due to the remarkable advances in mixed-integer programming (MIP) of the last years, various MIP models for training an Optimal Classification Tree (OCT) have been proposed. Along the research line of Margin Optimal Trees [1], we present an alternative mixed-integer quadratic formulation to construct multivariate OCTs. The proposed model defines the decision rules of the tree as maximum margin hyperplanes following the Support Vector Machine (SVM) paradigm along the binary tree structure. Further, we exploit the decomposable structure of the model to develop a tailored algorithmic approach able to leverage the SVM nature of each subproblem. First, the algorithm has been tested on non-linearly separable synthetic datasets in a 2-dimensional feature space to provide a graphical representation of the maximum margin approach. Finally, the method has been tested on benchmark datasets from the UCI repository in order to evaluate its computational efficiency and the generalization capabilities of the generated trees.

3 - A novel and effective integer linear programming formulation for the train routing selection problem

Anna Livia Croella, Fabio Furini, Ivana Ljubic, Bianca Pascariu, Paola Pellegrini, Pablo San Segundo

Given a set of train routes associated with route costs and a set of compatible route pairs associated with pairing costs, the train routing selection problem (TRSP) aims to assign a route to each train, minimizing the sum of the route and pairing costs while ensuring pairwise compatibility among the selected routes. This problem holds significant practical importance, particularly in rail traffic management, where it plays a central role. We propose a binary quadratic programming formulation for the TRSP and employ a linearization technique from the literature, with a linear number of additional variables and constraints, to derive a novel and effective integer linear programming (ILP) formulation. Exploiting the specific nature of the TRSP, we devise a technique to enhance the strength of the linear programming (LP) relaxation of the ILP model, resulting in a significant improvement in its computational performance. We obtain in this manner the first effective exact approach for solving the TRSP with proven optimality. Our approach is capable of solving real-world instances of the French railway network in very short computational times. These instances have typically been tackled only by heuristic algorithms in the existing literature. Furthermore, we theoretically and computationally compare the new linearization against the classical one with a quadratic number of additional variables and constraints and against the only ILP model from the literature.

1 - Estimating Greenhouse Gas Emissions Through Deep Learning: A Gradient-Based Analysis of Input Impact

Manizheh GhaemiDizaji, Laleh Behjat, William D. Rosehart

We aim to propose a novel approach to estimating greenhouse gas (GHG) emissions by leveraging deep learning techniques and conducting gradient-based analysis to assess the influence of various inputs on CO₂ emissions. The inputs considered encompass a range of socio-economic and environmental factors, including Gross Domestic Product (GDP), transportation modes, and energy generation mix. By constructing a deep neural network architecture, we aim to capture the complex relationships between these inputs and GHG emissions, enabling robust estimation and prediction capabilities. Furthermore, our approach integrates gradient-based analysis to elucidate the relative contribution of each input towards overall emissions output. This allows for a granular understanding of the impact of individual factors, empowering policymakers and stakeholders to prioritize interventions effectively. Through iterative modifications of input values and analysis of resultant emission outputs, we can delineate the share of each input in driving emissions variations. This research presents a promising methodology for GHG emissions estimation and analysis, offering insights into the intricate interplay between socio-economic drivers and environmental outcomes. By combining deep learning with gradient-based analysis, we provide a powerful framework for informing climate policy decisions and facilitating sustainable development strategies.

2 - Environmental Sensitivity and Emission Limits

Salvador Sandoval Bravo

We posit an oligopolistic competition scenario in which two companies compete for an identical product, while consumers have different preferences for them. One product uses a technology that generates pollution, while the other uses cleaner technology. Consumers show a degree of environmental sensitivity in favor of organic products over pollutants. The host country's government sets an optimal emissions limit for the polluting company. This emission limit is positive when the discomfort caused by pollution and/or the level of environmental awareness is high enough. However, the optimal emission limit is zero if the discomfort caused by pollution and/or the level of environmental awareness is low enough. The intensity of environmental awareness has a negative effect on the optimal limit of permitted emissions.

3 - Toward Climate-neutral Aviation - The Market Adoption of Sustainable Aviation Fuels using Agent-based Modeling

Sandra Venghaus, Jakob Rohner, Ali Ebadi Torkayesh

The European Union (EU) pursues a progressive policy course towards sustainable development, reflected in the implementation of a portfolio of targeted policies such as, e.g., the Green Deal, the Fit for 55 Package. While many of the EU's sectors have experienced declining emissions, the transport sector, aviation in particular, has shown the opposite trend. To address this challenge, the EU has launched a political effort to enforce a green transition from fossil fuels to sustainable aviation fuels (SAFs). In 2023, the European Commission adopted the ReFuelEU Aviation Directive that mandates the uptake of SAFs, including power-to-liquid fuels and advanced biofuels, as part of a larger effort to achieve sustainable aviation. Analyzing and modeling the effects of such political frameworks is crucial for understanding their long-term impact on industry developments and consumer behavior. A sound system understanding to explore both direct but also indirect effects provides a crucial precondition for effective policy-design. For this purpose, an integrated approach based on joint System Dynamics

and Agent-based Modeling is used to analyze the economic and environmental impact of the current regulatory framework on market development options of SAFs. Findings indicate that efficient regulatory interventions can support the transition and that achieving the green transition requires a shared responsibility among customers, industry players, and policymakers.

Airplane Boarding

Stream: Public Transport Optimization

Invited session

Chair: [Florian Jaehn](#)

Chair: [Simone Neumann](#)

1 - Airplane boarding, multi criteria decision making and the evolution of the universe

Eitan Bachmat

We will consider airplane boarding as a paradigm in multi criteria decision making. In particular, we will consider ranking according to two criteria which could be SAT and GPA scores for students or risk and treatment efficacy for patients. We will relate the process of ranking students or patients to the process of airplane boarding and see that they are both related to the evolution of the universe from initial conditions.

2 - Minimizing the Airplane Boarding Time by Passenger-Seat Assignments

Felix J. L. Willamowski

Airline passengers usually have their seats selected or assigned before arriving at the gate in the airport. We investigate the impact of the passenger-seat assignment on the boarding completion time, especially when considering a central decision-making process that takes place when passengers are already in line. Different seat assignments may result in different boarding completion times, which directly influence the turn-around time of an airplane. Identifying seat assignments that minimize boarding time can therefore provide airlines with significant cost savings. We introduce the problem of assigning passengers to seats while minimizing boarding time in the context of combinatorial optimization, study the computational complexity of the problem and develop exact, approximation, and heuristic algorithms. In addition to a theoretical analysis, we compare these algorithms in a computational study. Furthermore, we investigate an online variant of assigning passengers to seats—proposed in Jaehn and Neumann's section on future research—and present results on the competitive ratio.

3 - Geometrical optics inspires fast boarding with slow passengers

Sveinung Erland

Airlines try to reduce the boarding time by letting certain groups of passengers enter the queue at the gate in a specific order. Slow passengers use long time to clear the aisle and block other passengers from reaching their seats. We show that a significant proportion of slow passengers can be permitted without increasing the boarding time, by using a simple Slow-in-the-Back-First (SBF) boarding policy that consists of only two groups. The policy is superior to several other group policies that are based on expected differences in aisle-clearing times, e.g., due to hand luggage.

The practical SBF policy allows for only slightly fewer slow passengers than a corresponding optimal "lens" policy, which on the other hand is hard to implement. The lens policy is based on the same principle as an optical lens and is optimal in the sense that no fast passenger can be replaced by a slow passenger without increasing the boarding

time. A geometric representation of the queue position and row designation of each passenger and a Lorentzian metric enable computation of the asymptotic boarding time when the number of passengers is large. The analytical asymptotic results are corroborated by simulations with a realistic number of passengers.

We also show how the SBF-policy can be adjusted to include a specified proportion of slow passengers that exceeds the critical upper limit, with limited increase in total boarding time.

4 - Big Data Visualization to Unveil Key Differentiated Service Dimensions of the Airlines Performances in COVID-19 Aftermath

Praowpan Tansitpong

This study explores how operational decisions regarding a quality-differentiated product line determines the overall success of a multi-product planning in airline market by using optimized integrated gradients of global airline industry from 2012-2022. Data visualization techniques are assigned to define contours and color shades in product and service design due to seat configuration, space allocation, seat design in time variants. In order to understand product variety dimensions, airline decisions are sliced into multiple cubic dimensions and assigned into different contoured colors, due to constrained in capacity in cabin deck and seat options, the density of colors returns individual decision made by each airline for given origin-destination of flight operations. The results suggested that critical areas of optimal product line choice are dependent not only on price discrimination and segmentation strategy, but the airlines with efficient aircraft layout favors service differentiation strategy in order to perform well in the airline market. The study reveals the interconnected relationship between constraint decisions and operational outcomes, shedding light on how factors such as space for passenger interactions, efficient seat configuration design, and in-flight seat design collectively impact both market share and load factors.

1 - Modeling product allocation problem for split orders and solving via clustering algorithms

Nihal Erginel

Product allocation problem is a warehouse management that concerns allocate the products to the storage positions in a warehouse or to the warehouses in multi-warehouse problem. If the orders split to the several warehouses, the cost of picking them up is a non-added value facility. So, the aim of product allocation problem is to determine which product should be located to the which warehouse to minimize the cost of handling and transportation activities of the split orders. In multi-warehouse problem, trucks can visit more than one warehouse to pick up customer orders if an order split to others warehouse. In this study, we aim that is to minimize the number of visited warehouses for total orders under capacity of warehouse and demand of orders. The assumption is the one product can only storage to the one warehouse. The mathematical problem is constructed and solved with GAMS 38.3.0. Also, product allocation problem is a clustering problem in which products can be clustered with respect to the number of warehouses. In this study, k-means algorithm is used for clustering the products to the four warehouses. It is shown that the similar results are obtained from mathematical problem and clustering algorithm.

2 - Design of Novel Resilience and Risk Management Model for Sustainable Supply Chains

Giray Resat

This study presents a novel solution methodology to cover sustainability objectives by synchronizing risk and resilience impact estimations for multimodal freight transportation industry. Minimization of total cost, time, and carbon emissions by using augmented [U+03F5]-constraint method are outlined under multi-objective mixed integer optimization model. Also, approach is shown as comparative analysis, after defining some pre-processing, symmetry breaking steps, valid inequalities, and logic cuts. After identifying fourteen different risk factors for multimodal transportation system, if the most critical risk factor occurs, there will almost 380% increase in total logistics cost and 210% increase in time, respectively. Decision makers can use alternative Pareto solution sets and information about potential impact of different risk factors over sustainability in their risk management systems. Therefore, some pro-active action plans can be proposed for dynamic environments and improve the logistics systems reliability under different supply disruptions.

3 - MCDM Analysis for the Selection of a Location for the Freight Macro Consolidation Centre - Portsmouth Case

Mohanad AL-Behadili, Djamila Ouelhadj, Andrew Bullock, Graham Wall

The high rate of population growth in the UK leads to an increase in freight transportation activities and shortage of urban space. This in turn raises negative impacts in urban areas such as congestion, pollution, etc. In addition, the largest contributor of emissions in urban areas is transportation, which produced about 24% of carbon emissions in the UK and 22% in Portsmouth in 2020. Freight transportations have negative environmental, economic and social impacts. To tackle such problems, this paper investigates the potential of the establishment of a macro consolidation centre to consolidate freight flows between suppliers and customers. This research is part of the Solent Future Transport Zone project (FTZ) funded by the UK's Department for Transport and led by Solent Transport. This paper has developed a Multi-Criteria Decision-Making (MCDM) framework using Analytic Hierarchy Process and Best Worst Method to determine a suitable location for a macro consolidation centre for the city of Portsmouth. The three main sustainability criteria proposed for the selection of the location include Environmental, Economic and Social. Each of these criteria has sub-criteria that are designed to meet the needs of the study area. The results show the efficiency of the MCDM framework and the sustainability criteria in determining the most suitable site for the macro consolidation centre in Portsmouth.

4 - Examining the Impact of Horizontal Collaboration on Individual Logistics Service Providers within Synchronomodal Networks

Shafagh Alaei Zordehi, Javier Durán-Micco, Cathy Macharis, Koen Mommens

Horizontal collaboration, alongside with vertical collaboration, is one of the essential elements of synchronomodal transport. Collaboration requires information sharing, among all involved organizations, even if they are competitors. Yet, implementing collaborative systems encounters significant challenges, such as lack of trust among potential participants and concerns about losing competitiveness. To address this challenge, we develop a simulation model of a synchronomodal network to study the interactions between different players in the network as well as the impact of horizontal collaboration on individual logistic service providers. The results show that while collaboration yields benefit for the overall system, these advantages are not evenly distributed among all players, and certain entities may even experience losses under specific circumstances. Our model visualizes these disparities and can be used to design compensation schemes that encourage logistic service providers to participate in collaborative systems. Ultimately, this model provides insights into the advantages and obstacles of horizontal collaboration in synchronomodal and in general logistics networks and can be useful for designing more equitable and sustainable logistics systems.

Crowdsourcing Logistics

Stream: Transportation

Invited session

Chair: Diana Jorge

1 - Equitable Workload Allocation in Vehicle Routing Problem with Heterogeneous Drivers

Iman Dayarian

We introduce an equitable crowdsourced last-mile delivery model using the Nash Social Welfare (NSW) solution to ensure fairness among drivers. In the private logistics sector, fairness considerations are growing due to pressures to improve workload equity. Our model aims to maximize driver equity and efficiency while ensuring company efficiency by putting a cap on the deviation of the company's cost from the least-cost solution value. We formulate the problem as a variant of the vehicle routing problem with a nonlinear objective function inspired by NSW's approach. A column generation method is developed to solve the problem, and a computational study evaluates the model's behavior in terms of company cost, drivers' profit, and equity.

2 - An Approximate Dynamic Programming Approach for a Crowdshipping Platform

Emma Innocente, Jean-Sébastien Tancrez

Spurred by the growth of online shopping, parcel delivery has grown rapidly, driving a need for cost-effective last-mile delivery. Amidst this growth, sustainability concerns are gaining prominence. Crowdshipping leverages crowdsourcing for the personalized delivery of freight, turning ordinary citizens into couriers for the distribution of small items. In this collaborative delivery system, individuals already traveling from an origin to a destination take charge of all or part of the delivery, taking a package along with them and making a stop along the way to drop it off, potentially reducing freight trucks and enhancing sustainability. To fully leverage the potential of crowdshipping, real-time matching of crowdshippers to parcels is crucial, considering spatial and temporal uncertainties in crowdshippers' and parcels' availability. Due to its size, the dynamic assignment problem considered in our article cannot be solved with conventional dynamic programming methods. Using approximate dynamic programming with value function approximation, our algorithm learns value functions offline through a training horizon, enabling efficient decision-making. This adaptive learning algorithm provides nonmyopic behavior yet requires only solving sequences of assignment problems no larger than would be required with a myopic algorithm. Initial results demonstrate its superiority over myopic solutions in reducing delivery distances.

3 - Optimizing the dynamic heterogeneous order-courier assignment problem for instant deliveries

Diana Jorge, Tomás Rocha, Tania Ramos

Instant delivery services gained popularity for delivering meals to city dwellers, and the range of products available for delivery has significantly expanded. These platforms utilize crowdsourced couriers who operate their own vehicles, leading to a diverse courier fleet. In the face of great competition to attract and retain both customers and couriers, it is crucial for companies to develop advanced decision support tools. Such tools must be capable of generating real-time assignments that fulfill the expectations of service providers, customers, and couriers. To address the dynamic and complex nature of matching orders with couriers, considering the varied fleet and specific order-vehicle requirements, a time-driven simulation-optimization decision support tool was created. This tool is designed to manage incoming orders, couriers' availability, real-time courier location updates, and factors like dynamic traffic congestion and different regional speed limits for different vehicle types. The efficacy of the developed tool was validated through tests using instances from existing literature, where it demonstrated its capacity to effectively tackle the assignment problem. Furthermore, when applied to a real-world case study, the proposed tool achieved a reduction of roughly 4.5% in total delivery

times—from the moment an order is placed to its arrival at the customer—compared to the original assignments.

4 - Parcel delivery planning with multiple parcel services and crowdworkers

Dominik Stampa, Stefan Nickel

There are several more or less established options for transporting parcels. Classic parcel delivery is usually done by van, with only a few parcel services available. These parcel services operate in large areas, e.g., across an entire country. Looking at recent developments, there are services that only operate in small areas, e.g., a city, and deliver parcels, for example, by bike. In recent research, delivery per drone or autonomous vehicle is investigated, usually restricted to smaller areas like cities or city districts. In addition to these different types of delivery services, we want to consider commuters as a resource for parcel transportation. The inclusion of commuters could open up previously untapped transport capacity potentials. Commuters with car could make their transport capacity available on the way to work and transport parcels as crowdworkers. If we integrate all these types of delivery services and crowdworkers into a general delivery network, we can split parcel deliveries among several parties. A single parcel can then be transported by several delivery services or crowdworkers. We present an algorithm, based on a shortest path approach, that, given a customer's delivery order, computes a transport from sender to recipient independently of other orders. With this approach, we can immediately provide the customer with transportation proposals based on different objectives such as delivery time, emissions, or price.

Risk management and valuation of financial contracts

Stream: Modern Decision Making in Finance and Insurance

Invited session

Chair: *Eric André*

Chair: *Bertrand Tavin*

1 - Insurer's management discretion: Self-hedging participating life insurance

Peter Hieber

The majority of articles on participating life insurance contracts with guarantees assumes a deterministic and exogeneously given investment strategy for the insurer's assets, for example a geometric Brownian motion. However, the insurer may strategically adjust the risk of its asset investments depending on liability values. We look at the optimal design of such investment strategies with the aim to reduce insurer's risks. In the extreme case, the insurer may hedge its liabilities ("self-hedging"). This is joint work with Karim Barigou (Université Laval, Canada).

2 - Merged LSTM-MLP for option pricing

Rita Pimentel, Morten Risstad, Erlend Stegavik Rygg, Jacob Vinje, Sjur Westgaard, Cassandra Wu

This paper proposes a new merged LSTM-MLP deep learning approach for option pricing. The model has the advantage of combining time series data with static data. On the one hand, it learns from historical asset returns, as well as considers the option characteristics at the pricing date. This configuration does not need an estimation for an explicit volatility measure, improving upon existing methods. We test it on S&P 500 European call options from 2015 to 2022. The model excels in accuracy and risk-adjusted returns, showcasing its usefulness in real-life applications.

3 - A constrained simulation approach to robust risk management of derivative products.

Bertrand Tavin

This paper considers the problem of assessing and hedging the risk carried by a portfolio of non-standard derivative products managed with a parametric model. We first formalise the problem and define the framework in which it can be solved by using a constrained simulation approach with respect to the model parameters. Our approach is suitable for an agent who may be agnostic with respect to a prior model and who wish to account for expert views on the range of possible models. Instead of breaking them into several subproblems, the proposed methodology has the important advantage of answering the risk measurement and hedging question in one step. Namely, the agent needs to run the simulation just once to get the desired answers. We present numerical results obtained with recent market data when applying the method to a portfolio of variance swaps and forward-start options valued with stochastic volatility models. In this project we apply classic Operational Research techniques, namely constrained simulation, in a novel manner to risk measurement and hedging of trading portfolios.

Invited session

Chair: *Krissada Tundulyasaree*

1 - Integrated Planning of Train Path and Rolling Stock Assignment in Railway Freight Transportation

Louis Fourcade, Stéphane Dauzere-peres

The optimal use of critical resources, particularly train paths and rolling stock, plays a pivotal role in enhancing the operational efficiency and cost reduction of railway freight companies. Determining the right timetables for train paths is essential when integrating the selection of train paths and the assignment of the rolling stock. In this research, we explore heuristic approaches for this integrated problem where practical operational constraints such as maximum load, maximum weight, delivery time and freight car shunting in classification yards are taken into account. We propose an Adaptive Large Neighborhood Search (ALNS) heuristic based on a Pickup and Delivery Problem with Time Windows and Transfers (PDPTWT) to define the train path catalog that is required for the routing decisions of the rolling stock. A column generation approach is then used for the assignment of individual demands to train paths. Real-world data on the French railway network is used to validate the proposed approach, and good solutions are obtained in reasonable computational times. Our integrated approach is also compared with a sequential approach.

2 - Planning of Inductive Charged Passenger Buses on Airport Aprons

Niklas Pöch

Given the increasing importance of sustainability in the aviation sector due to climate change, electrifying ground vehicles on airport aprons is one way to reduce emissions. Dynamic inductive charging, which wirelessly charges vehicles while moving, is especially suitable for airport apron vehicles as it eliminates downtime for charging electric vehicles compared to conductive charging. We focus on scheduling electric passenger buses on airport aprons that use an inductive charging infrastructure to charge their batteries. Specifically, we investigate which vehicle should perform each service trip, whether it is transporting passengers from a gate to an airplane or from an airplane to a gate. We aim to ensure the reliable operation of these buses and avoid delays and breakdowns due to empty batteries. We present a formulation of the problem using a mathematical model. With this model, we want to evaluate different inductive charging infrastructures.

3 - Policy Setting for Integrated Freight and Passenger Transportation

Krissada Tundulyasaree, Layla Martin, Rolf Van Lieshout, Tom van Woensel

Public authorities use policies to encourage freight forwarders to shift towards more sustainable modes of transportation. In an integrated freight and passenger transportation setting, freight forwarders can choose between unimodal (truck) or multimodal (truck and scheduled train/barge) transport, minimizing their operational costs. To promote more sustainable transport, public authorities levy taxes on road transport and subsidize scheduled services. In this study, we propose a bi-level model where the authority sets road-access taxes and rail/water-access charges while freight forwarders select the modes of transportation. Due to the inherent computational complexities, we solve the problem using a bi-section algorithm for the upper level and Adaptive Large Neighbourhood Search for the freight-forwarder's lower level problem. We find that it is usually optimal to make the scheduled line free and to set the tax sufficiently high to stay within a predefined budget. However, increasing subsidies and taxes gives marginal returns on modal shift and mileage reduction. Due to decreased routing efficiency, a budget-neutral policy results in considerable cost increases for the freight forwarders. The policy maker can allocate a budget to keep tax at an acceptable level while still promoting modal shift.

4 - One Million ... and Beyond! Solving Huge-Scale VRPs in a Handful of Minutes

Daniele Vigo, Luca Accorsi

We propose a new dataset of Capacitated Vehicle Routing Problem instances which are up to two orders of magnitude larger than those in the currently used benchmarks. Despite these sizes might not have an immediate application to real-world logistic scenarios, we believe they could foster fresh new research efforts on the design of effective and efficient algorithmic components for routing problems. We provide computational results for such instances by running FILO2, an adaptation of the FILO algorithm proposed in Accorsi and Vigo (2021), designed to handle huge-scale CVRP instances. Solutions for such instances are obtained by using a standard personal computer in a considerably short computing time, thus showing the effectiveness of the acceleration and pruning techniques already proposed in FILO. Finally, results of FILO2 on well-known literature instances show that the newly introduced changes improve the overall scalability of the approach with respect to the previous FILO design.

via a column generation algorithm. The result can be shown to provide both a tighter bound than previously known as well as a simple heuristic for the control problem. To allow for more general basis functions and possibly good value function approximations and corresponding heuristics, we also discuss simulation-based approximate dynamic programming (sb-ADP). In a numerical study, we show that our sb-ADP heuristic typically obtains expected revenues close to our theoretical upper bound and better than a simple ALP-based policy. The quality of the sb-ADP, however, highly depends on the allotted computation time. For increasingly complex customer preferences, the time required for strong performance can be prohibitive.

2 - Airline Cancellation, Loadfactor, and Weather

Fredrik Odegaard

Airlines occasionally either delay or completely cancel scheduled flights. Often the explicit reason is inclement weather, however, other factors, including loadfactor, might influence the delay/cancel decision. This paper presents an empirical analysis of US airlines flight cancellations considering loadfactor and weather at origin and destination. The data spans May 2022 to June 2023.

3 - Boosting Hotel Profits: The Power of Enhanced Cancellation Predictions

Ryusuke Kimura, Kimitoshi Sato

The hotel industry faces the uncertainty of reservations and cancellations. Although dynamic pricing provides appropriate discounts for last-minute cancellations, it is not always possible to fill vacancies unless there is sufficient demand. Therefore, it is important to know how the accuracy of cancellation forecasts affects the results of dynamic pricing in practice. In this study, we analyze the relationship between forecast accuracy and expected returns using actual data on room reservations and cancellations in a region in Japan. The results show that a 10% improvement in forecast accuracy results in a 2% improvement in revenue. We also show that this improvement simultaneously improves consumer surplus by lowering the average sales price and improving the load factor. Furthermore, the improvement is more effective during the peak season when the number of potential customers is higher.

4 - Reserved product pricing with dependent and normally distributed reservation prices

Thomas Archibald

Reserved product pricing (RPP) is a strategy used by firms selling two (or more) products to consumers. Under this strategy, products are offered for sale individually and consumers who purchase only one of the products is later offered a discount on the other product. Prior analysis has shown that RPP can be more profitable than other bundling strategies under the common assumption of independent and uniformly distributed reservation prices. We use a simulation model to investigate the performance of RPP with more general assumptions about reservation prices. The results show that RPP remains an attractive strategy provided not too many customers anticipate the discount and modify their behaviour to purchase only one product initially. The main finding is that the optimal RPP strategy is relatively robust to the correlation in reservation prices.

1 - Dynamic Pricing of Empty Seats in the Transportation Industry under the Nested Logit Model

Davina Rauhaus, Christiane Barz, Jochen Gönsch

We suggest a dynamic pricing model for selling "empty seats" - seat reservations for extra space in addition to regular reservations. Such extra space tickets share the main product's resources and are a significant revenue-generating opportunity when coaches, trains, or airplanes frequently depart with many empty seats. We formulate the problem of a transportation company that sells tickets in the same compartment (1) without a seat reservation, (2) with a seat reservation, and (3) with a seat reservation and extra space as a Markov decision process. To address the resulting curse of dimensionality, we follow two approaches. First, we use approximate linear programming (ALP) with an affine value function approximation. We solve the resulting linear problem

1 - Risk assessment framework for project's activities with conditional expectation

Ken-ichi Suzuki, Tetsuo Iida

Evaluating the impact of an activity on a project is essential for risk management. Therefore, over time, various researchers have proposed different risk indicators, including criticality index (Van Slyke, 1963), significance index (Williams, 1992), Crucially index (Williams, 1992), management-oriented index (Madadi & Iranmanesh, 2012), criticality-slack-sensitivity index (Ballesteros-Pérez et al., 2019), and more. However, while each indicator conveys a certain aspect of the activity's behavior, they have faced criticism for sometimes presenting an evaluation that is counter-intuitive to actual practice, and the debate on the choice of risk indicators is ongoing. In this presentation, we first discuss the desirable properties that risk indicators should possess. These include consistency with an overall risk measure, linkage to a risk-reducing action, and risk decomposition. Based on these properties, we propose a risk assessment framework that uses conditional expectation. In the proposed framework, we measure the overall risk with the expected delay to a reference time point and define the risk indicator by an activity's expected duration conditioned with the delay and criticality of the activity. Finally, we demonstrate the effectiveness of the new indicators by applying them to the cost allocation for stochastic CPM and the buffer sizing for the buffer allocation problem.

2 - An efficient linear reformulation for project portfolio optimization problems

Ming-Hua Lin, Jung-Fa Tsai

With the rapid evolution of technology and the constant changes in the business environment, many enterprises assign different tasks as projects. Therefore, project management performance is critical to the success of the enterprise. There are usually multiple projects executed concurrently in the organizations. Project portfolio management significantly influences project management performance due to the limited available resources and the interdependency between projects. Project portfolio selection is one of the most critical issues in the project portfolio management process. Allocating available resources to an optimal set of projects will result in the most benefits. This study considers a project portfolio selection problem that discusses selecting an optimal subset of projects from a set of candidate projects for maximizing benefits with an effective and efficient use of limited resources. The original mathematical model of the project portfolio selection problem is a nonlinear integer programming problem that is hard to solve for finding a globally optimal solution. This study utilizes a novel linearization approach that efficiently transforms the project portfolio selection problem with cross-product terms as a mixed-integer linear program solvable for finding a globally optimal solution. Compared with current methods, the proposed method uses much fewer continuous variables to linearly reformulate the problem. Numerical examples are presented to demonstrate that t

3 - Analyzing Delay Litigation Cases of Public Building Construction Using Text Mining Techniques

Ying-Mei Cheng, Wei-Jie Huang

In long-term construction projects with complex work interfaces, disputes that arise during construction often leave contractors unable to complete the work within the contractually agreed timeframe. This results in varying degrees of loss, compelling the contractors to seek a resolution of responsibility through litigation to safeguard their rights. Construction project delays have been extensively studied, with researchers often delving into analyses of factors influencing project schedules. The current study examines legal documents from litigation cases to observe the relationship between factors influencing project schedules and the outcomes of disputes commonly seen in litigation. This involves consolidating Supreme Court rulings on project schedule extensions and utilizing text mining tools to analyze and explore the cause-and-effect relationships of schedule-influencing factors in construction dispute litigation cases. The aim is to provide insights into whether resorting to the courts is a valuable option during contract disputes in construction projects.

4 - Analysis of demand and planning of capacity for the judiciary

Femke Boelens, Richard Boucherie, Anne Zander

Efficient planning of judicial capacity is crucial for ensuring a timely resolution of court cases. Accurate predictions of demand are essential for capacity planning. The demand of the court consists of cases that need to be resolved, either by one or multiple hearings or in writing. We analyze the arrival process of cases to the court and formulate a negative binomial regression model to predict the court demand on a weekly basis, taking seasonality into account. We test our prediction model on real-life data of the Dutch judiciary. Subsequently, we formulate an optimization model for planning capacity for one future year based on these predictions, considering capacity constraints, aiming to minimize the waiting time. We model the problem as a non-homogeneous queue with a time-dependent arrival rate and a service rate that is subject to control. By incorporating insights from a transient analysis of the queueing model, we solve the optimization model by stochastic programming, compare our capacity planning to the status quo, and run experiments to test several choices of capacity planning.

1 - The minimum covering Euclidean ball problem: review and report

Mark Cawood, Lin Dearing

Efficient primal and dual algorithms have been developed recently by the authors for the n -dimensional minimum covering Euclidean ball problem of several types. These include the minimum covering ball of a given finite set of distinct points, the minimum covering ball of a given finite set of balls each with different radius and center, and the minimum covering ball of a set of distinct points with weighted Euclidean distance between the points and the center of the covering ball. Each problem type corresponds to an equivalent one-center location problem.

The common approach for each algorithm is a search-path method, where the search path is determined by the intersection of bisectors of pairs of points. Each problem has a different structure for the bisectors of pairs of points (hyperplanes, hyperboloids, and hyperspheres, respectively). The step size along the search path is computed exactly at each iteration. Each point on the search path is primal (dual) feasible and satisfies complementary slackness for the primal (dual) algorithm.

Example problems are presented for each problem type and illustrate the bisectors, their intersection, and the optimality conditions. Computational results are presented.

Current work is presented on the combined problem of finding the minimum covering Euclidean ball of a given set of balls with weighted distance. The bisector of a pair of points is a quartic surface.

2 - Congested Hub Location Problem with Price-dependent Demand

Ata Jalili Marand, Pooya Hoseinpour

This study investigates a congested hub location problem with the aim of optimizing a service provider's profit by determining hub locations, capacities, and prices for serving commodities. The study incorporates a price-dependent demand function with a general functional form and models hub operations as M/G/1 queueing systems to address congestion effects. The problem is initially formulated as a mixed-integer nonlinear program, which is subsequently transformed into a

mixed-integer second-order cone program, demonstrating solvability with standard off-the-shelf solvers. Through numerical analysis, the study evaluates the influence of different demand functional forms and service time constraints on the optimal network configuration and the service provider's profitability.

3 - The Planar Obnoxious Facilities p-Center Problem

Pawel Kalczynski, Zvi Drezner

The p-center problem is one of the classical location analysis problems. It involves locating one or more facilities (in the plane or on the network) among multiple demand points while minimizing the largest distance between a facility and a demand point. Recent papers present novel solution techniques that allow for solving large-scale planar p-center problems. However, p-center models involving obnoxious facilities have yet to be investigated. Obnoxious facilities emit or inflict nuisance, such as noise or pollution, on the demand points. This nuisance propagates "by air," so it can be reduced by locating the facilities further away from the demand points. However, this new property makes p-center models nonconvex and more challenging to solve. We formulate the planar obnoxious p-center problem as a general non-linear program and reformulate it as a nonconvex quadratically constrained optimization problem. We present two solution techniques: an optimal (within tolerance) one involving the linearization of non-linear constraints and one involving a multi-start approach with a local solver (without the optimality guarantee). The effectiveness and efficiency of our techniques are demonstrated on both generated and commonly used instances of the p-center problem. In addition, we investigate the impact of the obnoxious property on the planar p-center problem difficulty and solution quality.

1 - Fleet deployment and slot exchange in liner shipping alliance with carbon emission trading system

Yadong Wang, Shenghui Zhu, Cagatay Iris

Shipping alliance has become a prevalent cooperation form among major container shipping companies in recent decades. By forming an alliance, shipping companies can better satisfy the shipping demand and improve capacity utilization and profitability. At the same time, the shipping industry has become an important source of global greenhouse gas emissions. Faced with the emerging worldwide maritime carbon emission trading system, the shipping alliance needs to redesign its fleet to control carbon emissions and reduce its negative effects on the profit of the alliance members. This paper considers the fleet deployment and slot exchange problem in shipping alliance with the consideration of carbon emission trading system. A mixed integer nonlinear programming model is first proposed to simultaneously optimize the fleet deployment, the ship sailing speed and schedule for each shipping service, the slot allocation and exchange for each alliance member, and the container routing, with the objective of maximizing the alliance total profit (freight revenue minus the ship operating cost and emission trading cost) and minimize the variation of the profit rate among alliance members. A tailored spatial branch-and-bound algorithm is proposed subsequently considering the structure of the problem to obtain the global optimal solution. Numerical experiments also demonstrate the effectiveness of the model in emission reduction and profit improvement for a shipping alliance.

2 - Proposal to reduce carbon footprint through the use of h2v in tugboats in ports

Lorena Bearzotti, Luciano Nuñez, Maria Isabel Vega, Javier Maturana-Ross

The importance of transportation in society and its significant contribution to polluting emissions from internal combustion engines using fossil fuels highlight the necessity of transitioning to a renewable energy matrix. Green hydrogen emerges as a viable option to mitigate this impact. This transition aims to reduce emissions in maritime transportation progressively. The maritime sector plays a crucial role in global trade and transportation, accounting for a substantial portion of fossil fuel consumption and associated emissions. The adoption of cleaner and sustainable technologies in maritime transport not only aids in emission reduction but also fosters innovation and the development of eco-friendly solutions. Enhancing research and development in energy-efficient technologies and environmentally sustainable practices within maritime transport is essential for combating climate change on a global scale. Transitioning towards green hydrogen and other renewable energy sources in maritime transport signifies a significant step towards a cleaner and more sustainable future. This shift prioritizes emission reduction and environmental protection as key objectives. By leveraging green hydrogen and renewable energy sources, the maritime industry can pave the way for a greener, more efficient, and environmentally conscious approach to transportation, setting new standards for sustainability and emission reduction in the sector.

3 - Column generation algorithm for smart-split stacking strategy at automated container terminals

Yuanjun Feng, Dongping Song

Container stacking strategy determines the positions of incoming containers in the storage yard, which plays a vital role in improving the efficiency and productivity of container terminals and reducing the energy consumption of equipment and vehicles. The smart stacking strategy for import containers aims to create relocation-free stacks - named smart stacks, by utilizing customer information, thus reducing the retrieval time of import containers. There are two variants of stacking policies under the smart stacking strategy: split policy and non-split policy. The split policy, where containers from the same customer are allowed to be split between smart stacks and non-smart stacks, is superior to the non-split policy. This paper investigates the import container stacking problem under the split policy. The problem is first formulated as a mixed-integer programming (MIP) model to minimize the total working time of the yard crane. By enhancing the representation of certain variables, we then develop an improved MIP model, which is computationally more efficient than the original model when using CPLEX as a solution tool. We also propose a column generation algorithm to solve the improved model. Extensive computational experiments are conducted to demonstrate the effectiveness of the proposed models and the efficiency of the proposed algorithm.

4 - Optimising electric vehicles charging and energy management in port microgrids

Cagatay Iris

Seaports, as substantial consumers of energy, aim to adopt energy management systems in response to rising energy costs and a commitment to sustainable operations. Many ports are shifting to electricity as their primary energy source, opting for fully electrified equipment like electric vehicles (e.g. battery AGVs) instead of carbon-intensive alternatives. This paper presents a mixed integer linear programming model designed to address the integrated planning and energy management challenges faced by seaports utilizing a port microgrid. The planning module of the model determines the allocation of electric vehicles and related equipment, as well as the scheduling of EV charges, specifying the energy usage for each one-hour period. Additionally, the planning module decides the berthing duration for each ship, influencing the hourly energy consumption of the port. The energy management aspect involves aligning energy demand and supply, considering various energy pricing schemes, bidirectional energy trading among different sources (such as the utility grid, renewable energy sources), and integrating energy storage systems. The study's findings suggest that the implementation of smart grid technology, represented by the port microgrid, can yield substantial cost savings compared to traditional setups. Notably, efficient charge planning and battery management within microgrid systems enable ports to achieve significant cost reductions.

1 - Pricing Options with a Compound CARMA(p,q)-Hawkes model

Andrea Perchiazzo, Lorenzo Mercuri, Edit Rroji

Recently a novel self-exciting point process has been introduced in the literature, featuring a continuous-time autoregressive moving average intensity process. Such a model, named CARMA(p,q)-Hawkes, extends the traditional Hawkes process by integrating a CARMA(p,q) framework instead of an Ornstein-Uhlenbeck intensity. As a matter of fact, the proposed model maintains the same level of mathematical tractability as the Hawkes process (e.g., infinitesimal generator, backward and forward Kolmogorov equations, joint characteristic function); but it shows enhanced capability in reproducing complex time-dependent structures evident in several market data. Based on this framework we propose a compound CARMA(p,q)-Hawkes model incorporating a random jump size independent of both the counting and intensity processes, which serves as a key component for a new option pricing model. We conduct an analysis to assess the effectiveness of this pricing model in replicating the volatility surface observed in market option data.

2 - Forecasting the worst: is implied volatility forward-looking enough?

Carlo Confalonieri, Paola De Vincentiis

The paper backtests the accuracy of 1-day Value-at-Risk (VaR), computed with variance-covariance methodology, using various alternative methodologies for estimating the risk factor's volatility. The aim is to gauge whether using option-implied volatility (IV) produces superior results compared to other time-series based measures. In particular, we want to test if a forward-looking estimate - reflecting the sentiment of market investors - is more capable of capturing the tail behaviour of returns distribution during crisis periods, characterized by volatility spikes. The empirical analysis is performed on the S&P500 Stock Index, using both the VIX Index and VIX-1day Index, recently introduced by the Chicago Board Options Exchange. The crisis analysed are the pandemic period and the months following Russia's invasion of Ukraine. Our results contradict our initial hypothesis, showing that IV-based VaR tend to be underestimated during market turbulences, both in terms of frequency of realized losses exceeding the threshold and in terms of average magnitude of the excess losses. However, quite a different picture emerges when we use the new VIX1D index, instead of the traditional VIX. The preliminary evidence indicates that the 1-day implied volatility derived from near term options may be effective for estimating VaR and superior to alternative methodologies.

3 - Value-at-Risk of an Option Portfolio Under Different Scenarios. A Proposal of a More Reliable Market Measure

Giacomo Gaggero, Pier Giuseppe Giribone, Duccio Martelli, Sanmoy Mukherjee

Value at Risk is one of the most widely implemented methods in the financial sector for assessing the traditional market risk associated with a portfolio. We focus our attention on nonlinear pay-off derivatives such as options, proving the effectiveness of the proposed methodology also for non-standard options. To calculate the future projections of the analyzed portfolio, we implement a full-repricing forward-looking Monte

Carlo method. Based on data from the last five years, we compute for each of the eleven stocks, on which options are written, the volatility implementing six different techniques (Close-to-Close, High-Low, High-Low-Close, EWMA, GARCH(1,1) methods and Implied Volatility), the dividend using two alternatives (Historical and Implied measures) and the drift using both traditional econometric approaches like ARIMA and innovative like LSTM technique. Subsequently, having estimated the volatility and the drift, we have implemented those for simulating the underlying prices for the next periods using a Geometric Brownian Motion. Doing this, we have used only the most prudential scenarios for the projection of the assets. We have consequently considered all the possible combinations for these inputs in the option pricing model, estimating the most reliable forward-looking fair value distributions of each option over the next days through 20,000 daily simulations. Value at risk has then computed taking the percentiles of this distribution.

1 - Lagrangian and Other Relaxations for the Urban Snow Removal Problem

Kaj Holmberg, Roghayeh Hajizadeh

Snow removal problem in cities is a challenging task in nordic countries. Doing the snow removal efficiently is important. Since the amounts of snow vary a lot from day to day, and from year to year, fixed plans are not the best. Optimization of the snow removal tours could save much time and money.

We study the multi-vehicle urban snow removal problem from a mixed integer programming perspective. It is a very hard problem, and obtaining the exact optimum seems to be out of reach. Therefore, we study relaxations of the problem. Our goal is simply to find the best bounds for the optimal objective function value that is possible in limited time.

Since the problem has many sets of constraints with complicated structures, using Lagrangian relaxation might be beneficial. We discuss different possibilities of relaxing sets of constraints and develop a Lagrangian heuristic which consists of a suitable Lagrangian relaxation of the problem, a subgradient optimization method for solving the Lagrangian dual, and procedures for obtaining feasible solutions. The heuristic has been implemented and applied to artificial and real life city networks.

Extensive computational tests show that the lower and upper bounds can be improved.

2 - A Branch and Price for the Min Max Multi-Trip Location Arc Routing Problem

Teresa Corberán, Isaac Plana, Jose Maria Sanchis

In this work, we address the Min Max Multi-Trip Location Arc Routing Problem (MM-MT-LARP). We consider a depot from which a set of P trucks, each one carrying a drone, must travel to P out of D available points, where the drone is launched. Each drone has a limited autonomy which allows it to fly a maximum time L before having to get back to the launching point to change its battery so that it can start another route. Once the drone has completed all its routes, the truck goes back to the depot. The goal of the MM-MT-LARP is to determine the launching point for each truck and find a set of drone routes for each truck, each one starting and ending at its launching point and with flight time not greater than L , in such a way that all the drones' routes jointly traverse all the given edges and the largest total time of

all the trucks (time of traveling to the launching point, flight time of the drone and time of traveling back to the depot) is minimized. In this talk, we present a route-based formulation for the problem and a branch-and-price algorithm to solve it, as well as some preliminary computational results on a set of instances with different characteristics.

3 - On the Chinese Postman Problem With Load-Dependent Costs

Paula Segura Martínez, Isaac Plana, Jose Maria Sanchis

The Chinese Postman Problem (CPP) is a classical arc routing problem whose objective is to find a minimum cost tour on a connected undirected graph G that traverses each edge of G at least once. An extension of this problem introduced in the literature is the Chinese Postman Problem with load-dependent costs (CPP-LC), in which the cost of traversing an edge depends on its length and also on the weight of the vehicle at the moment the edge is traversed. This is motivated by the intention of reducing pollution in transportation, since the level of emissions from a vehicle is influenced by factors beyond the distance traveled, such as its load. Two mathematical programming formulations and two metaheuristic algorithms have been proposed in the literature for the CPP-LC solution. We present in this work a new mixed-integer linear programming formulation for the CPP-LC, and propose some valid inequalities to reinforce it. We also develop a study of the incompatibilities of a subset of variables from the formulation and describe all the cliques of the underlying intersection graph, categorizing them into five families of inequalities that are valid for the problem. We design a branch-and-cut algorithm for the CPP-LC solution based on this formulation that incorporates the separation of all the valid inequalities proposed. Some computational results obtained with our new exact procedure are presented and compared with those provided in the literature.

4 - The Covering Arc Routing Problem

Isaac Plana, Mercedes Landete, Juanjo Peiró, Jose Maria Sanchis

Transporting valuable or dangerous goods may require constant surveillance to prevent potential thefts or incidents. Such supervision can be carried out by installing cameras or hiring security guards, which entails a monetary investment. In this work, we introduce the Covering Arc Routing Problem (CovARP), that combines arc routing and location problems. Let us consider an undirected graph with a cost associated with the traversal of each edge and a subset of edges (required edges) that must be traversed to perform some kind of service. Additionally, there is a set of potential monitors that can be activated or not. Each monitor has an activation cost and covers a certain set of edges if it is activated. The CovARP consists of both finding a closed path (tour) that traverses all the required edges at least once and determining a set of monitors that should be activated, so that all the edges traversed by the tour are covered by at least one active monitor, while minimizing the sum of the tour cost and the activation cost of the monitors. We present an integer linear formulation for this problem and a branch-and-cut algorithm. This algorithm has been tested on a randomly generated set of instances. We have analyzed three different situations: when the activation cost of the monitors is clearly higher than that of the tour, when the cost of the tour outweighs the activation cost of the monitors, and the balanced case in which both costs are comparable.

1 - Stochastic dominance in decision making under uncertainty

Milos Kopa

Stochastic dominance is a statistical tool developed for comparing the random variables among each other. In financial applications, these random variables usually represent random returns of the considered assets or portfolios. The paper focuses on portfolio selection problems with stochastic dominance constraints for various orders of stochastic dominance relations. Firstly, the tractable necessary and sufficient conditions for particular probability distributions are discussed. Secondly, these conditions are employed in the static and dynamic portfolio selection problems. Finally, the extensions for the case of vector comparisons are presented. The theoretical results are accompanied by empirical examples.

1 - Mixed Integer Programming and Heuristics Approaches for Clustering with Local Feature Selection

Cem Iyigün

In this study, we work on a clustering problem where it is assumed that the features identifying the clusters may differ for each cluster. Number of clusters and number of relevant features in each cluster are given in advance. A center-based clustering approach is proposed. Finding the cluster centers, assigning the data points and selecting relevant features for each cluster are performed simultaneously. A non-linear mixed integer mathematical model is proposed which minimizes the total distance between data points and their cluster center by using the selected features for each cluster. Different linearization methods have been used for solving the problem. Besides, two different heuristic algorithms have been developed by taking into account the nature of the mentioned problem. Experimental results have been presented.

2 - Anytime algorithm configuration

Elias Schede, Kevin Tierney

Optimization algorithms contain parameters that greatly influence their behavior, such that finding good parameters with automated algorithm configuration (AC) tools has become a critical component in the algorithm design process. Optimization algorithms often possess the anytime property, meaning they can be stopped at any time during their execution and provide a feasible solution. However such algorithms are not specifically targeted by current AC techniques. Setting the parameters of anytime algorithms is especially difficult, as the parameters ought to provide robust performance across varying execution times. Traditional AC methods address this challenge by finding

a one-size-fits-all parameter configuration, however finding a schedule of configurations, each targeted to a different runtime, can lead to better overall performance. We introduce a novel AC method for configuring anytime algorithms that produces viable configuration schedules that assign different configurations to different runtimes. Our proposed method harnesses an early termination mechanism for unpromising configurations using a machine learning model, and uses two novel MIP formulations to discard configurations and to create the configuration schedule, respectively. The resulting schedules can be used by decision makers to choose a suitable configuration given a specific runtime for an anytime target algorithm.

3 - Using Clustering to Strengthen Decision Diagram Bounds for Discrete Optimization

Michael Römer, Mohsen Nafar

Offering a generic approach to obtaining both upper and lower bounds, decision diagrams (DDs) are becoming an increasingly important tool for solving discrete optimization problems. In particular, they provide a powerful alternative to other well-known generic bounding mechanisms such as the LP relaxation. A standard approach to employ DDs for discrete optimization is to formulate the problem as a Dynamic Program and to compile a DD top-down in a layer-by-layer fashion. To limit the size of the resulting DD and to obtain bounds, one typically imposes a maximum width for each layer which is then enforced by either merging nodes (resulting in a relaxed DD providing a dual bound) or by dropping nodes (resulting in a restricted DD providing a primal bound). The quality of the DD bounds obtained from this top-down compilation heavily depends on the heuristics used for the selection of the nodes to merge or drop. While it is sometimes possible to engineer problem-specific heuristics for this, a generic approach relies on sorting the layer's nodes based on objective function information. In this talk, we propose a generic and problem-agnostic approach that relies on clustering nodes based on the state information. In a set of experiments with different knapsack and scheduling problems, we show that our approach outperforms the classical generic approach, and often achieves drastically better bounds both with respect to the size of the DD and the time used for compiling the DDs.

1 - Modelling of piece-wise linear concave constraints in continuous covering problems

Liding Xu, Claudia D'Ambrosio

We study continuous set covering on networks. The covering condition has a representation as a piece-wise linear concave constraint, which we formulate as a disjunctive system. We propose three MILP reformulations based on indicator constraint, big-M, and disjunctive programming techniques to formulate the disjunctive system. We classify new and old formulations and conduct experiments to compare them.

2 - A Knowledge Compilation Take on Binary Polynomial Optimization

Silvia Di Gregorio

The Binary Polynomial Optimization (BPO) problem is defined as the problem of minimizing a given polynomial function over all binary points. The main contribution of this paper is to draw a novel connection between BPO and the problem of performing model counting over the $(\max, +)$ semiring on Boolean functions. This connection allows us to give a strongly polynomial algorithm that solves BPO with a hypergraph that is either beta-acyclic or with bounded incidence treewidth.

This result unifies and significantly extends the known tractable classes of BPO. The generality of our technique allows us to deal also with extensions of BPO, where we enforce extended cardinality constraints on the set of binary points, and where we seek k best feasible solutions. We also extend our results to the significantly more general problem where variables are replaced by literals. Preliminary computational results show that the resulting algorithms can be significantly faster than current state-of-the-art.

3 - Generalized convexity applied to branch-and-bound algorithms for MINLPs

Ksenia Bestuzheva

One of the key properties of convex problems is that every stationary point is a global optimum, and nonlinear programming algorithms that converge to local optima are thus guaranteed to find the global optimum. However, some nonconvex problems possess the same property. This observation together with empirical evidence that local search solvers often find global optima of nonconvex problems such as optimal power flow and pooling has motivated research into generalizations of convexity. This presentation proposes a new generalization which we refer to as optima-inconvexity: the property that only one connected set of optimal solutions exists. We discuss conditions for optima-inconvexity and its applications within spatial branch-and-bound algorithms for mixed-integer nonlinear programs.

4 - M-Decomposable Sets in Integer Programming

Diego Moran

An M-decomposable set is a closed convex set which is the sum of a compact convex set and a closed convex cone. We present properties of these sets in the context of integer programming. In particular, we present properties of their integer hull, some cutting plane closures and subadditive duality.

1 - A comparative study of large-margin strategies for Active Learning

Annabella Astorino, Antonio Fuduli

Training a classifier is a challenging task as it typically requires a significant amount of labelled data, while most available samples are unlabelled. For instance, in the field of diagnostic imaging, labelling medical images requires the expertise of a specialist. In this case, Active Learning (AL), a machine learning approach that aims at minimizing the number of samples used in the learning phase, can assist the decision maker. A performing AL algorithm selects the most informative data points based on a defined metric and passes them to a human labeler, who progressively adds the labeled data to the training set. The motivation for adopting such a strategy is related to the significant effort required in terms of costs and man-hours to label the data.

The concept of active learning is based on the consideration that not all data points are equally important for training a classifier model. Therefore, AL algorithms select only the most valuable data instances. The key point is how this selection is made. This work focuses on possible sampling based on large-margin strategies of the Support Vector

Machine (SVM) type. The distance to the separating hyperplane can be considered a reliable metric for measuring the model confidence or certainty on unlabeled data samples. In this study, the role of samples close to the classifier boundary is investigated by comparing supervised and semi-supervised approaches. Preliminary numerical experiments are reported.

2 - Utilising decision-making methods and online tools to accelerate sustainable renovation investments: Insights from a stakeholder engagement approach

Aikaterini Papapostolou, Ioanna Andreoulaki, Vasilis Kotrogiannis, John Psarras

The building sector is the largest consumer of energy in Europe. Energy efficiency is fundamental for the cost-effective transition towards a decarbonised energy system. The renovation rates of buildings reveal that there is an urgent need for action by leveraging private capital in investments. To this end, multiple actors of the value chain need to be engaged to enhance communication among them, overcome barriers and increase chances for renovation projects to be financed. The involvement of key stakeholders is useful to get alternative perspectives, which stimulates shifting the focus from project activities to intended outcomes in the early stage, and to clear communication of the scope of an energy efficiency project in terms of objectives, milestones and outputs. The specific paper introduces a stakeholder engagement process analysing the impact that an online marketplace promoting energy efficiency investments in buildings would have to the energy and financing community. This is done through a concrete methodological approach based on an institutionalised engagement process of the relevant stakeholders. Key findings, which have emerged from a dedicated survey and a training workshop with regards to the market needs and critical uncertainties affecting the building renovation investments popularity, support the co-creation of an energy efficiency marketplace that enables project aggregation and matchmaking with financing institutions in a standardised manner.

3 - Performance comparison of machine learning models in detecting the best-performing methods for the resource-constrained single-and multi-project scheduling problem

Weikang Guo, Mario Vanhoucke, José Coelho

Priority rules are the most used methods in many commercial software tools for scheduling projects under limited resources because of their ease of implementation, intuitive working, and fast speed. The branch-and-bound (B&B) procedure is the most common way to deal with the resource-constrained project scheduling problem to find the optimal solution in a finite number of steps. Meta-heuristics are the most effective methods to solve project scheduling. Although these methods have been developed, no single method has been shown to be the best. To fill this gap, we rely on machine learning classification and ranking models to find the relation between the characteristics of the project instances and the performance of solution methods.

This study not only aims to compare the performance of different machine learning models but also proves that machine learning can be used to solve the resource-constrained multi-project scheduling problem (RCMPSP). The contribution is threefold: First, we extend two types of machine learning models to solve the multi-project scheduling problem. Second, we extend both machine learning models to priority rules, branch-and-bound procedures, and meta-heuristics, respectively. Third, we compare the performance of two types of machine learning models on the three categories of solution methods. An extensive computational experiment is set up to compare the performance of machine learning models with the existing methods from the literature.

4 - Assignment optimization with decision-dependent completion times for trademark application evaluation

Shabnam Kilic, Ozlem Karsu, Taghi Khaniyev

In this work, we consider an assignment problem with decision-dependent completion times which is motivated by a real-life application in trademark evaluations. We formulate the problem of assigning evaluations to agents as a Mixed Integer Programming (MIP) model

to help decision-makers better assign workers to evaluation tasks, considering their expertise and current workload. The aim is to minimize the backlog level of the office, which is quantified by the total number of tardy jobs. We provide two alternative formulations and explore their computational performance on a large number of test instances. We integrate both linear and neural network prediction models by using machine learning algorithms and evaluate the improvements in the total number of tardy jobs.

Behavioural OR meets Information systems

Stream: Behavioural OR

Invited session

Chair: Michael Leyer

1 - The intention to work in the metaverse concerning the quality of working life: A PLS-SEM approach

Thomas Paetow

The Quality of Working Life assesses the quality of the relationship between employees and their work environment, reflecting the well-being of employees concerning their professional lives. The metaverse, as a new form and location of work, is poised to alter the work environment significantly. Considering these developments, examining individuals' intentions to work in the metaverse is crucial. This study aims to analyze the intention to work in the metaverse and its effects on the Quality of Working Life. A designed questionnaire will be used to gather empirical data to test the hypotheses. The analysis will use Partial Least Squares Structural Equation Modeling (PLS-SEM) to model and verify relationships between variables. The results are intended to provide insights into employees' intentions to work in the metaverse against the context of Quality of Working Life. Anticipated influential factors include work-life balance and psychosocial well-being in the metaverse. The PLS-SEM analysis should validate our theoretical model and facilitate the quantification of relationships. This research provides theoretical and practical implications, e.g., for designing digital work environments, and lays the foundation for future studies in this area.

2 - Trust, Risk, and the Decision to use Smart Contracts: A Dual-Study Analysis

Wieland Müller

This study examines the influence of trust and risk on individuals' decision-making regarding the adoption of smart contracts. Two quantitative studies were conducted in the United States to conduct an in-depth analysis of trust, risk, and the decision to use smart contracts. The first study presents a trust model for smart contracts based on Hoff and Bashir's (2014) dimensions of trust and Lemieux et al.'s (2019) findings on trust towards distributed ledgers. The second study builds on the findings of the specific trust dimensions, using Mayer et al.'s (1995) trust model and Stuck et al.'s (2021) role of risk in automation. The results highlight the importance of situational social trust and trust in technology for individuals' risk behavior and the decision to adopt smart contracts. It also shows how perceived risk is moderated and how risk-taking propensity positively influence usage intentions. The study emphasizes the importance of trust dynamics and risk considerations in the adoption of smart contracts and makes a valuable contribution to the field with its original findings and comprehensive analysis. It contributes to theory by providing a novel, multidimensional model of trust and an integrative approach to examining the relationship between trust and risk behavior and its influence on decision making in an organizational context. In practice, this study provides insights for the design and implementation of smart contracts in various industries.

3 - Behavioural Real Options Analysis of Projects using Machine Learning

Marius Wittke

Investment projects typically involve flexibility of action, also known as managerial flexibility. Managerial flexibility has a value that can be quantified using Real Options Analysis. In order to exercise managerial flexibility, information is required. Unlike financial options, there is typically no objective market information available for real options. Instead, the decision maker usually has noisy information. This means that the current value and relevant factors affecting the project have to be estimated and therefore decisions have to be made on the basis of imperfect information. These estimates are subjective and can be affected by cognitive biases. Cognitive biases are systematic errors in judgement and decision making. As a result, cognitive biases can lead to poor decisions, which can reduce the value of managerial flexibility. In this context, the question arises as to how wrong decisions due to cognitive biases can be avoided. Since cognitive biases can be interpreted as a deviation from rational action, it would be helpful to be able to identify an optimal policy as a benchmark. However, this can be challenging, especially with noisy information. Machine learning algorithms could be useful in deriving an optimal policy. The basic idea is that wrong decisions lead to opportunity costs that can be minimized by an algorithm based on a simulation model. Neural Networks and Reinforcement Learning could be used to make optimal decisions.

4 - The Effect of Overconfidence on the Use of Recommender and Decision Support Systems

Ayşegül Engin, Rudolf Vetschera

To benefit from digitization, decision support systems and recommender systems find wide business-to-business applications with the increasing digitization. To ensure that organizations benefit from implementing such systems, how employees interact with them as users is crucial. Certainly, modifications to system elements, such as design elements, can improve usability by mitigating the gap between what the user can work with and what the system offers. However, cognitive biases such as the hindsight bias and the overconfidence bias affect the usability of the system and cannot be mitigated through a system element modification. The present study focuses on the effect of overconfidence as a consequence of hindsight bias on the use of personalized recommender systems and a more general decision support system. This study aims to contribute to the literature on recommendation systems by showing that users benefit from recommender systems depending on their cognitive biases differently. Using an experimental approach, the study looks into the use of recommender systems and general decision support in repeated decisions with higher order structures. Because of the higher-order structure, the designed decision situation for this study entails uncertainty. To disentangle decision behavior from outcome, which is affected by the uncertainty posed by decision situation, the study uses a reinforcement learning model to describe decision-making behavior of users.

Austria by 2030, we linked a bottom-up electricity system model (ATLANTIS) with a top-down macroeconomic model (DYNK). This integrated approach enables a comprehensive analysis encompassing both energy and socio-economic dimensions, factoring in the continental European electricity grid constraints through ATLANTIS rather than relying on simplified representations. The study reveals the growing importance of gas-fired power plants in balancing the intermittent output from RES-E, indicating that these plants will continue to influence electricity market prices. It highlights the potential socio-economic benefits, including an 18% GDP growth by 2030 (compared to 2017) under Austria's renewable expansion act (EAG) scenario, driven by population growth, export expansion, and increased total factor productivity, alongside a 20% rise in final electricity demand. A sensitivity analysis around CO₂ pricing suggests higher electricity costs and reduced GDP growth, hinting at a slight dip in electricity demand versus the EAG scenario. The findings underscore the necessity for enhanced renewable integration and storage solutions to fully decarbonize Austria's electricity system, emphasizing the critical role of flexible gas-fired generation and the potential economic implications of transitioning to a more sustainable energy mix.

2 - Screening Curves in Net-Zero Energy Systems: Insights and Limitations

Maximilian Walde, Julian Keutz, Oliver Ruhnau

Various dispatchable power generation technologies can complement each other due to their diverse economic characteristics. Screening curves have been used to determine optimal mixes of power plant capacity from load duration curves since the 1970s. Starting with only fossil and nuclear generation technologies, recent applications have incorporated variable renewable energy sources by considering residual load duration curves. However, the applicability of screening curves to net-zero energy systems with growing shares of renewables remains untested. Here, we aim at filling this gap by creating net-zero screening curves and comparing the derived optimal capacity with the results of a linear model minimizing total power system costs. In a first step, we exploit the screening curve approach to identify cost-optimal decarbonized dispatchable technologies as a function of renewable energy shares and across a wide range of cost assumptions. In a second step, we process the linear model and investigate aspects that are neglected in the screening curve model, i.e. the deployment of short-term storage and time-variant prices of synthetic fuels. Preliminary results show consistent technology choice for both the screening curve and linear model. However, the optimal capacity differs with rising shares of renewables, particularly for the technologies with lowest and highest variable cost. This raises concerns about the applicability of screening curves in net-zero energy systems.

3 - Heterogenous investors in energy markets

Christoph Weber

With decarbonization, numerous and heterogenous new generation units are installed. Decisions on such investments depend on multiple, partly not observable factors. Many long-term energy models are yet formulated as linear programs and are therefore prone to abrupt changes in primal variables ("penny-switching"). Discrete choice models deal with heterogeneity in individual decisions and avoid penny-switching. Here an approach is presented to incorporate such decision modelling in a non-linear, convex optimization problem, along with technological and system constraints. The problem is reformulated using the entropy function of information theory and transformed to an essentially linear program with a few exponential cone restrictions. A first application investigates wind and PV investments across Germany based on the novel approach and compares the outcomes to the results of standard LP formulations. It is shown that the regional spread of investments increases when unobserved heterogeneity is taken into account.

4 - Linking modelling to generate alternatives and market equilibria - On the economic interpretation of near-cost-optimal solutions in energy system models

Market-based analyses in long-term energy system models

Stream: Energy Markets

Invited session

Chair: [Jonas Finke](#)

1 - Assessing the Energy and Socio-Economic Impacts of Renewable Energy Expansion in Austria by 2030

Robert Gaugl, Sonja Wogrin

To evaluate the impact of increased shares of renewable energy sources in electricity (RES-E) on wholesale electricity prices and demand in

The energy transition requires complex decisions, which can be supported by energy system models. Modelling to generate alternatives (MGA) is a method to generate diverse, near-optimal solutions and address the structural and parametric uncertainties of such models. In energy planning, MGA generates almost cost-minimal but societally more feasible model outcomes. However, it neglects the economic feasibility resulting from (potentially lacking) profitability of investments based on market revenues, which in contrast is guaranteed for unconstrained cost-minimal solutions under certain conditions. Therefore, this paper aims at developing a market-economic interpretation of near-cost-optimal alternatives. Methodologically, we use results from multi-objective optimisation and the first-order Karush-Kuhn-Tucker conditions to show equivalence between MGA and cost minimisations with additional cost terms. On the way, we augment MGA to generate only Pareto-optimal solutions, i.e. to avoid costs that do not contribute to higher diversity between alternatives. Economically, the introduced cost terms can be interpreted as capacity-based subsidies or penalties that, as an intervention to an otherwise perfect market, lead to the same outcome as found with MGA. Such an intervention guarantees profitability and hence market-based feasibility. Practically, we demonstrate and validate our theoretical findings for the case study of a multi-national power system model.

Kidney Exchange I

Stream: OR in Health Services (ORAHs)

Invited session

Chair: Joel Joris Van de Klundert

Chair: Twan Dollevoet

1 - Novel immunological and optimization strategies to optimize Saudi Kidney Exchange

Michal Mankowski

Living donors are often incompatible with their intended recipients. Kidney exchange matches one patient and his or her incompatible donor with another pair in the same situation for an exchange. We studied novel immunological such as applet matching to optimize the Saudi National Kidney Exchange Program (SNKEP) involving a number of Saudi transplant centers and their pool of patients. Cross-hospital kidney exchanges allow an increase in the likelihood of finding the matching pairs, improve the qualities of the matches, and provide. We modeled the impact of new immunological matching strategies on overall graft survival.

2 - Integer linear programming formulations for the kidney exchange problem with reserve arcs

Maxence Delorme, Wendy Liu, David Manlove

We are interested in the kidney exchange problem with reserve arcs (KEPRA), an extension of the classical kidney exchange problem in which one is allowed to select arcs that do not appear in the compatibility graph (called reserve arcs, or RA). We study two optimization problems: (i) what is the maximum number of transplants given an upper bound on the total number of RA that can be used, and (ii) what is the minimum number of RA that is necessary for every recipient to receive a kidney.

This problem is motivated by a recent breakthrough in the field of kidney transplant reported by the newspaper "The Guardian" stating that "researchers have successfully altered the blood type of three donor kidneys in a gamechanging discovery that could significantly improve the chances of patients waiting for a transplant finding a match".

We show that, even though existing integer linear programming (ILP) formulations can easily be extended to the KEPRA, solving these models with a state-of-the-art ILP solver requires a long computation time due to the fact that the compatibility graph is complete. We then show

that there always exists an optimal KEPRA solution in which every cycle contains at most one RA, and use that property to develop an effective variable reduction procedure for each model. We finally use that property to extend the well-known position indexed chain-edge formulation to the KEPRA and show that it clearly outperforms all the other ILP models.

3 - Strategyproofness of Credit Mechanisms for Kidney Exchange

Bart Smeulders

Increasing the scale of kidney exchanges leads to improved outcomes for patients, as it increases the possibility of compatible donors being present. One way to increase scale is by collaboration between different hospitals or countries. However, it has been shown that in single period settings, no strategyproof mechanisms exist to organize such collaborations. This has led to an interest in credit mechanisms which function over multiple time periods. Individual agents reveal pairs to the collaboration, and receive credits in return. These influence which transplants are selected, where more credits lead the choice of solutions that are more beneficial to the agent. Based on the transplants received, credits are subtracted. Such mechanisms can lead to fairer outcomes, but also potentially escape the impossibility of strategyproof mechanisms in single period settings. In this talk, we look in particular at credit mechanisms proposed by Klimentova et al. (2021) and Biro et al. (2020). These mechanisms divide credits equal to the number of transplants obtained in an optimal solution, and each transplants "costs" one credit. We discuss the strategyproofness of their proposed mechanisms, and more in general of all mechanisms sharing some important properties with these.

4 - Local stability in kidney exchange programs

Marie Baratto, Yves Crama, João Pedro Pedroso, Ana Viana

Kidney exchange programs allow patients with end-stage renal disease to receive a kidney transplant from a living donor. The maximization of the number of transplantations within a pool of potential donors and recipients is a combinatorial optimization problem that has generated abundant literature over the past 20 years. Several authors have pointed out the relevance of the classical literature on stable matchings in this context. However, the optimization of stable kidney exchanges has not been widely investigated. We extend recent work on stable exchanges by introducing and underlining the relevance of a new concept of locally stable exchanges. We show that locally stable exchanges in a compatibility digraph are exactly the so-called local kernels of an associated blocking digraph (whereas the stable exchanges are the kernels of the blocking digraph). We prove that it is NP-hard to determine whether a graph has a nonempty local kernel. Next, we propose several integer programming formulations for computing a locally stable exchange of maximum size. These formulations can be viewed as modeling the maximum local kernel problem in the blocking digraph. We conduct numerical experiments to assess the quality of our formulations and to compare the size of maximum locally stable exchanges with the size of maximum stable exchanges. It turns out that nonempty locally stable exchanges frequently exist in digraphs which do not have any stable exchange.

Behavior in group decision-making

Stream: Behavioural OR

Invited session

Chair: Femke Bekius

1 - Behavioural consequences of supporting open strategizing with OR methods

Jonan Raaijmakers, Femke Bekius, Vincent De Gooyert, Etienne Rouwette

Over the last two decades, strategizing developed from an exclusive endeavour towards a more decentralized approach that aims to empower stakeholders in strategic decision-making. This new stream in strategizing is named 'open strategy' and transforms the traditional exclusive strategic decision-making into a more inclusive and transparent process. Although open strategy is beneficial, e.g., increased diversity or quality of ideas, it also brings new challenges and dilemmas that as of now are unresolved by contemporary open strategy tools. We study open strategy processes in the Dutch energy, road, and drinking water context. From a literature study, we found that operational research (OR) methods can contribute to open strategizing, by resolving some of its dilemmas. Therefore, we apply participatory OR methods to support inter-organizational stakeholders in making strategically aligned decisions to tackle challenges that transcend organisational boundaries. We present findings from an ongoing study that aims to understand the behavioural consequences of OR-supported open strategy processes. We approach this study by investigating model-supported interactions on an individual level, how individuals add, remove, and change model elements, and, on a group level, how these interactions shape the path towards a group decision. Furthermore, we investigate the use of the outcomes from the intervention in the broader multi-organisational context, with evaluative interviews.

2 - Playing a card game in a workshop to generate decision objectives: pretesting the evaluation

Alice H. Aubert

Game-based approaches are increasingly used in participatory decision-making. Yet, rigorous evaluation of their effectiveness is often lacking. Typical challenges include small sample sizes, no control treatment, and no control for the potentially confounding factors. Sometimes, claims about potential benefits of the game are unaligned with the evaluation. I will present a framework for promoting a more robust evaluation of game-based approaches, based on an illustrative case. The illustrative case focuses on evaluating the effectiveness of playing a card game in a workshop designed to generate decision objectives for sustainable wastewater management. Specifically designed for non-experts, such as municipality council members, the card game targets the diverging phase of generating objectives and incentivize participants "collect" diverse criteria. Guided by the call for complementary data types in BOR and principles from the educational science, we concurrently developed a comprehensive evaluation process and the card game-based workshop. Our pre-test of the evaluation process with 10 students highlighted the complementary nature of quantitative and qualitative data types. Yet, challenges such as sample size and confounding factors remained. We suggest collaborative efforts among researchers to address these issues. The framework and insights from our illustrative case contribute to developing robust approaches to evaluate participatory interventions.

3 - Evaluating the impact of supporting group decision-making with participatory OR methods

Femke Bekius

Achieving sustainable transformations, in areas such as climate change, mobility, agriculture and food, health and ageing, has become an imperative goal of societies worldwide. Participatory OR methods are often used to support group decision-making in the context of sustainable transformations. It brings multiple stakeholders with different incentives and aims together and potentially results in a shared vision, perspective or decision. However, evidence about the impact of participatory OR methods on sustainability transformations is scarce. Evaluation of participatory OR methods happens in various ways and is generally performed in an ad-hoc manner. Moreover, evaluation takes place at various levels including the behavior of the individual, dynamics of the group, consequences for the organization, or impact on the larger system in which the transformation takes place. In this talk, I present a number of concepts which can be used to evaluate the process of decision-making in reaching sustainable transformations. Hereby, I distinguish between the different levels (individual, group, process, system) at which assessment can take place. In particular, I focus on the question: How do these concepts assess the "transformative potential" of OR-supported decision-making processes? To illustrate this I use case studies from different domains where participatory OR methods are used to support sustainable transformations.

4 - Learning to facilitate team discussions

Etienne Rouwette, L. Alberto Franco

Building an operational research model together with the team responsible for the issue at hand helps to elicit knowledge and create commitment to joint action. In these facilitated modelling interventions the facilitator has a central role. How can an analyst perform the role of facilitator? Furthermore, what is effective team facilitation? Understanding the rationale behind tasks helps the facilitator to translate generic advice on what to do, to the specific situation encountered. Our assumption is that the more the facilitator's behaviour is in line with these attitudes, the more effective they will be in supporting a team decision process. We describe five facilitator attitudes (helping, neutrality, inquiring, relational engagement, self-reflexivity), as well as the facilitator tasks aligned with each of these attitudes.

TC-12

Tuesday, 12:30-14:00 - Room: 13 (building: 116)

DSS in Agriculture

Stream: OR in Agriculture and Forestry

Invited session

Chair: *Aida Huerta-Barrientos*

1 - Integrated Production, Storage and Transportation Optimization in the Compound Feed Industry

Jasper van Doorn

Production scheduling and vehicle routing are both well known and widely studied problems within the field of operations research. However, in many practical settings a supply chain consists out of a sequence of different stages that all require some scheduling or routing. Rather than just optimizing the planning within each stage separately, a good synchronization between the different stages is crucial to prevent inefficiencies or infeasibilities. Especially when there is none or limited storage capacity between subsequent stages, bad synchronisation might lead to delays or even deadlocks. An integrated solution method is required to prevent this and obtain good synchronization over the entire supply chain. We propose a general framework for modelling such multi-stage problems and compare different integration strategies

The issue of multi-stage scheduling problems with limited intermediate storage especially arises for industries that are making a transition from make-to-stock towards make-to-order. A good example is the compound-feed industry, where storage is usually designed for large quantities of universal products. Due to changing customer requirements, the production changes more and more towards small quantities of many different personalized products instead. Since intermediate storage is not suited for this, this increases the need for good synchronization between production and transportation. We also provide results based on realistic data from this industry

2 - Vehicle routing problem to optimize pig deliveries to the abattoir

LuisM Pla, Yun Bao, Pol Llagostera Blasco

Nowadays, pigs are raised in large industrial-scale operations. The fattening farms operates under an all-in-all-out management policy. In general, the fattening period depends on the starting weight, batch homogeneity, feeding system, growth curve, reward system and chain management policies. Although pigs are fed with the same diet, not all of them reach market weight at the same time. Hence, partial sales produce better economic rewards. Once the old batch leaves, and before the new batch arrives, the facilities are cleaned and sanitized. The viewpoint of an abattoir collecting fattened pig from many different farms belonging to the same supply chain has not yet been considered. Farms vertically integrated sell their entire production to a single abattoir in agreement with the supplier contract signed with the integrator company in a long-term relationship. The routes to collect pigs and

the arrival to the abattoir need to be balanced over time and scheduled beforehand with uncertainty in pigs' liveweight to avoid workload peaks and a fair operation for the PSC. The problem is a vehicle routing problem with uncertain demand since the deliveries depend on the inventory of pigs. Thus, the objective is to formulate a mixed-integer linear-programming (MILP) model to optimize daily routes of trucks and transports of fattened pigs to the abattoir. A metaheuristic algorithm is proposed to approximate the solution of the model and to efficiently plan transportation.

3 - A Simulation Study for Agricultural Production Optimization

Zehra Kamisli Ozturk, Gurkan Ozturk

The aggravation of agricultural land misuse, alongside climate change and population growth, intensifies the pressure on agriculture to fulfill food demand. To address this challenge, urgent action is needed to implement sustainable land and forest management practices, expand cultivation areas, and enforce effective agricultural policies. Agriculture has historically been pivotal in sustaining livelihoods and economies, necessitating optimization in production planning and productivity to unlock its full potential.

There is limited research on agricultural production planning, particularly in Turkey. In this study, the focus is on conducting a 2-3 year simulation study to maximize revenue from agricultural products in a specific region. Using mixed integer programming, the study designs crop patterns for selected parcels and plans production accordingly. The GAMS software is utilized to solve the model.

In conclusion, addressing agricultural challenges through optimization models and simulation studies is crucial for fostering sustainable and efficient agriculture. This study contributes to optimizing agricultural production in Eskisehir, Turkey, underscoring the importance of customized solutions in agricultural planning and management.

4 - Using Expert Systems for simulation modelling of Hass avocado farming

Aida Huerta-Barrientos, Aidee Luz, Alma Elia Vera-Morales

In recent decades, the avocado fruit has gained popularity so many countries including United States, area among the biggest importer of this fruit, which implies a growing demand for this market. In Mexico context, micro and small producers are the ones who sustain most of the avocado exports in Michoacán. Decision making for the management of avocado production is a complex issue due to the large number of variables associated with developing a feasible production function and business plan. Although studies have been conducted by authors, the use of Expert Systems to modelling and simulation the farmer decision making process on Hass avocado production is still insufficiently explored. This paper addresses the need to design and implement an expert system for simulation modelling of Hass avocado farming for solving complex issues affecting the avocado production in Mexico context. First, we present the literature review about the use of Expert System tool for modelling and simulation the farmer decision making process on Hass avocado production. Second we describe the formulation and implementation of an Expert System for simulation modelling of Hass avocado farming using Netlogo software. In particular, we discuss a case study in Mexico. Then, the main results of our analysis are showed. Finally, we present our conclusions.

Impact of AI on Soft OR - B

Stream: Soft OR and Problem Structuring Methods

Invited session

Chair: Nuoya Tan

1 - The 'je ne sais quoi' of algorithms that foster human centric analytics design

Christina Phillips

There have been developments recently in interpretable and explainable AI as well as moves to understand ways to do human centred analytics design. As technology and the use of algorithms in business become more ubiquitous we need to understand what parameters in algorithm design can facilitate human centred approaches. Ways to do this ethically and sustainably become ever more pressing as business moves into a world of ESG reporting and increasingly cybernetic systems.

This talk initially outlines the parameters (defined by prior research) needed by algorithms and AI/ML techniques that make them amenable to integration with human practice. We then take a quick look at the philosophical underpinnings needed by research into cross paradigm work. This sets the stage for a tour of some currently available mathematical tools and techniques that can work with human practice and the contexts they are likely to work under.

2 - Augmenting Leadership Development with Generative Artificial Intelligence: Perspectives, Research Methods, and Future Directions

Nuoya Tan, Leroy White

Since the release of ChatGPT in 2022, Generative Artificial Intelligence (AI) has been transforming people's work lives. There is increasing research interest in leveraging Generative AI on human resource management, change management, innovation management, and management education. However, integrating Generative AI and leadership, especially leadership development, needs more attention. Previous work reviewed AI in learning and development and studied gender bias of AI-generated content in leadership training. To further existing research, we want to explore the potential of augmenting leadership development by leveraging Generative AI on leadership intervention and organizational context.

■ TC-15

Staffing and workforce planning and scheduling

Stream: OR in Health Services (ORAHs)

Invited session

Chair: Paula Antón Marañón

1 - Optimizing adaptive medical staff scheduling using recourse decisions amidst fluctuating patient demand

Markus Schüller, Jan Schoenfelder, Jens Brunner

Scheduling of medical staff represents a time-consuming task, even during periods of relatively stable patient demand and personnel availability. Since rosters are built based on long-term patient loads, significant discrepancies between expected and actual patient emergences may occur, especially in times of high volatility like the COVID-19 pandemic. To ensure adequate care in short-term, recourse decisions, such as extra shifts or transferring patients are necessary to cover high workload peaks in terms of demand. Nevertheless, exact forecasts about number of patients cannot be made for more than a few days in advance. This makes it nearly impossible for schedulers to anticipate unexpected demand when creating the upcoming schedule. In this work, we provide a Mixed-Integer Program (MIP) to (re-)allocate medical staff and therefore ensure appropriate care of all patients. Our MIP consists of a two-stage optimization model, which at first performs the initial schedule while on the second stage applying recourse decisions to cover realized patient demand. The expected workload is determined on forecasts about patient emergence and the acuity level

of patients by partners of the PROGNOSIS consortium. Our temporal scope encompasses a time horizon of one week. As patient demand is subject to numerous uncertainties, we evaluate scenario-based rosters by applying Sample-Average Approximation and provide generalized insights about short-term adjustments in personnel scheduling.

2 - Flexible shift scheduling of healthcare workers using column generation

David Ajit Kirpekar-Sauer, Jens O. Brunner

We consider a tactical shift scheduling problem, consisting of assigning health care workers in a hospital to shifts for handling a given number of tasks spread out over a fixed time horizon. We will implement a branch-and-price algorithm with the master problem assigning schedules to workers and the subproblem generating columns (shift schedules) to add to the master problem. The master problem will minimize the total cost of the chosen shift schedules and assigning outside workers to handle understaffing. The novelty in our approach is the use of a network flow model in the shift subproblem. Instead of formulating the subproblem as a MIP, we will make use of a novel network formulation. By traversing the network from the starting period to the end period a path, corresponding to a valid shift schedule, will be achieved. As such the subproblem can be solved, and a maximum reduced cost schedule can be found, by solving the shortest path problem for the graph. We will implement Dijkstra's algorithm with a labelling and readout step to find the shortest path through the network. In addition we will evaluate the possibility of scheduling flexible and inflexible workers to achieve a greater flexibility in the generated schedules. The fraction of flexible workers will be evaluated with varying degrees of flexibility to ensure a feasible application of the method. The method will be applied and tested on a number of test instances generated from real-world data.

3 - Optimizing physician allocation in an imaging diagnostic company

Maristela Santos, Vladimir Yuri Tasso, Caio Tomazella, Thiago Mariotti

Imaging diagnostic companies primarily rely on specialized medical workforce to deliver their services. However, there has been a stagnation in the number of specialist physicians over the years, making the workforce scarcer and more expensive. Another factor negatively impacting imaging diagnostic companies is health insurance providers' current financial status due to the sector's costs. Given this scenario, optimizing the allocation of medical resources in shifts is mandatory to achieve optimal outcomes, maximizing revenue and reducing costs associated with idleness. Idleness occurs when the demand is low for one examination unit, and physicians are over-allocated. In contrast, the demand for examinations in another unit can be high, but there is a need for more physicians. An integer linear optimization model was developed to allocate physicians in shifts and medical units, allowing physicians to be allocated in nearby units with available rooms. Additionally, two objective functions were analyzed: minimizing the number of unmet examinations, maximizing the lowest coverage considering units and shifts. Instances from an imaging diagnostic company were used for computational tests. When comparing the results obtained with data from the company, the model demonstrated a significant reduction in unmet demand and superior overall coverage, proving to be a practical approach to optimizing the allocation of medical resources.

4 - Labour scheduling for healthcare workers using efficient strategies

Paula Antón Maraña, Joaquín Pacheco, Julio Cesar Puche, Silvia Casado

Labour scheduling takes on special relevance in the healthcare field as most professionals work alternate shifts, which makes it difficult to balance work and personal life. One of the common practices is the allocation of schedules according to workers' preferences for each planning period. This results in models where professionals are assigned shifts in order to maximise their preferences while taking into account labour constraints. Usually these models include such constraints in their formulation, which results in excessively complex models. Thus, they

can only be applied in very small instances and require heuristic and metaheuristic techniques to solve real instances such as Variable Neighbourhood Search, Simulated Annealing, Tabu Search, Iterated Search and Genetic Algorithms, or even hybrid approaches, meta-heuristic or hyperheuristic strategies. In this work we propose a strategy applied to a real case of an elderly people's home, which consists of the following steps: a) to generate all possible sets of shifts ("patterns") that can be assigned to a professional that meet the labour constraints; b) to propose a model for assigning professionals to patterns. The labour constraints are satisfied, even if they do not appear explicitly, and the resulting model can be solved exactly on real instances of large size. This efficient strategy maximises the satisfaction of healthcare staff preferences, improving their productivity and the quality of patient care.

1 - A Neural Network Approach to Evaluate Expected Goals in Football

Giuseppina Dello Ioio, Stefania Corsaro, Zeldia Marino

The sports industry has a significant global reach, with a value of \$480 billion in 2023, which is expected to increase to \$629.81 billion by 2028. These data reveal various profit potentials, particularly for the betting industry, which generated a total turnover of EUR 1.41 trillion in 2022, of which EUR 730 billion was attributed to football alone. Due to its predominant role in the global sporting landscape and its significant economic impact, this work focuses on football, specifically on Expected Goals (xG). The accuracy of predicting xG plays a critical role in the financial and strategic decisions of football teams, as well as for investors and bookmakers, as it allows them to assess a team's performance and identify value bets more accurately. This work proposes an innovative Neural Network approach to predict Expected Goals in the main Italian league, Serie A, with the aim to provide a significant advancement in the application of predictive methods to football, opening new perspectives for analyzing and optimizing sporting and financial performance. Implementing this methodology could improve on-field performance and optimize team investments. Additionally, it could provide important insights for investors and bookmakers, enabling them to make more informed and profitable decisions in the context of professional football. This work is part of a larger research project that aims to evaluate financial contracts indexed to the performance of professional athletes.

2 - Some novelty on the xG model for Football Analytics

Rodolfo Metulini, Mattia Cefis

Within the realm of football analytics, an objective is to enhance the predictive capabilities and exploit the emerging tool known as the expected goal (xG) model for practical needs. The xG model aims to classify each shot, predict the final score of a game and evaluate strikers and goalkeepers performance. In previous works we proposed to match event data and composite indicators of player performance derived through Partial Least Squares - Structural Equation Model (PLS-SEM). The aim of this work is twofold: leveraging a dataset comprising tracking data from the Italian "Serie A" related to 2022/2023 season, we introduce to the existing model some original features, such as the Kos angle. Our results showcase intriguing findings in comparison to a benchmark (Understat), particularly in certain metric indices. Furthermore, the significance of performance composite indicators from PLS-SEM and specific tracking variables for the xG model is established. Afterwards, we exploit the performance of the model proposing a combination of machine learning and game theoretical approaches to assess the marginal contribution of single players in determining the

expected goal and the final game score. In particular, to achieve this latter goal, we adopt our xG as the cohesion function of a (generalized) Shapley value. By doing so, an instrument to jointly estimate the probability to score the goal and evaluate the role of each player in determining such probability is proposed.

3 - Expected Shots Concept for Football

Jirka Poropudas, Ville-Pekka Inkilä

In football analytics, various metrics for teams' offensive efficiency have been presented. As the objective of the game is to score goals, the number of goals scored and the number of shot attempts are the most obvious efficiency metrics. The commonly used expected goals (xG) metric estimates the quality of shot attempts by assigning them a probability of scoring based on shot location and other factors. However, all these metrics share a common weakness as they focus solely on possessions where shots are attempted, neglecting the broader context of play. This presentation proposes an approach where this limitation is avoided using event data consisting of the locations and times of various ball touches such as passes, dribbles, and shots. The data are then used to divide the match into possessions, i.e., continuous sequences of touches by one team, and to estimate the probability that a given touch on the ball is a shot attempt. These probabilities are used to calculate the shot probability for each possession, i.e., the possession's expected shots value (xS). This metric allows one to measure the quality of possessions and teams' ability to create scoring chances without restricting the analysis to shot attempts that actually took place. The proposed approach is compatible with various extensions such as the skill level and tendencies of individual players as well as a more detailed description of the game state as provided by player tracking technologies.

4 - Modelling tactical changes in association football using a Markov game

Nobuyoshi Hirotsu, Yuki Masui, Yu Shimasaki, Masafumi Yoshimura

We model tactical changes in association football as a Markov game. The pitch is discretised into nine zones and the states of the Markov game are defined according to the zone in which the ball is located in play, the team in possession, and the score. We first model tactical changes in a Markov decision process framework, wherein one team maximises their probability of winning. Then, we model tactical changes in a two-person zero-sum Markov game framework, wherein both teams maximise their probability of winning. Fundamental to our modelling is the notion that tactical changes impact upon transition rates. We verify the models using data from matches in a season of the Japan Professional Football League. We define a change in transition rates that can be realised by changes in tactics, and illustrate an example of optimal tactical changes when both teams can vary their tactics. The models we develop in the paper can support managers who are considering important decisions about substitutions and changes to formation, for example, when a match is in-play.

Since the late 1960's, Uruguay has developed an important system of housing cooperatives, which are an affordable option with many advantages over traditional options such as buying or renting a house or apartment.

A housing cooperative in Uruguay usually involves between 20 and 80 members. After the buildings are completed, a assignment is performed, giving to each member (as long as he/she continues to participate in the cooperative) the right to live in the assigned unit. The assignment is most usually performed by a random draw; which does not take into account individual preferences of the members over the different units.

In this presentation, we discuss the use of optimization methods to perform assignments which take into account the preferences of the cooperative members. Working with some Uruguayan cooperatives, we found that the total satisfaction, the minimum individual satisfaction were important criteria. Based on these insights, we developed a system employing a two-stage Mixed Integer Linear Programming (MILP) optimization model taking into account the minimum individual satisfaction and the total satisfaction. This system has already been applied in more than 30 cooperatives, involving more than 1000 habitational units, obtaining large improvements in comparison to random draws. Further work is being performed to include other criteria such as minimizing the difference between individual satisfactions.

2 - Sustainable and optimal transport corridors from China (Asia) to Europe reflecting geopolitical tensions in the region

Nahid Jafari

Building resilient and sustainable supply chains of goods and energy between Europe and Asia is a key challenge because of long distance, political risks, economic sanctions, environmental impacts, weather conditions, geoeconomics, and etc. In spite of existing routes passing Russia (the Northern Corridor) or Iran (the Silk Road), the European Union (EU) and Türkiye are more interested in initiating a new route in the middle of the two, bypassing Russia and Iran, is so-called the Middle corridor. In the Middle corridor, Azerbaijan, located at the intersection of the North-South and East-West transport routes, is recognized as an important transport and logistics hub. Meanwhile, the establishment of the Zangezur corridor by ending the conflict of Armenia-Azerbaijan may enhance diversifying energy supplies to Europe and beneficial for the global trading. The aim of this study is conducting a route optimization (intelligent, agility, cost-effective) followed by a data-driven analysis of influential factors and explore the various instruments of geoeconomic competition, then design a sustainable supply chains network.

3 - The Kerkenes eco-center in Anatolia: an interdisciplinary OR project

Gerhard-Wilhelm Weber, Francoise Summers

At previous EURO conferences, we presented, considered and contributed to the Kerkenes Eco-Village Project on Turkish rural countryside. At EURO 2024 we will inform about new aspects and related developments and view this project also from the overall and national aspects of urbanization, energy supply and education in Turkey.

Kerkenes Eco-Center, established by G. and F. Summers and supported by S.T Elias-Özkan, aims to promote sustainability through environmental studies. It pursues the following objectives: - To advocate the use of renewable sources of energy; - To act as a stimulus and a catalyst for environment-friendly building with appropriate materials and energy efficient designs; - To act as a dynamic experimental base for testing designs, materials and activities suitable for viable and sustainable village life. - To encourage village development and income generating activities that might halt and even reverse migration from rural areas to the cities.

We will relate the project with overall needs in Turkey, be it in the rural countryside or in the big cities, with regard to the demand for natural gas and for better primary school education in all social classes.

4 - Transformative approaches to urban sustainability: a case study of Bozcaada, Canakkale, Turkey, and circular economy strategies in developing countries

Eylul Sadanoglu

This research pioneers a transformative path towards urban sustainability in developing countries, employing a Theory of Change (ToC) framework. Focused on Bozcaada, Canakkale, the study integrates circular economy principles, emphasizing a dynamic approach to sustainability assessment. Through the lens of the ToC, this research explores the anticipated impact of strategic interventions on the urban sustainability landscape. The methodology involves a multifaceted approach, incorporating sustainability assessment, network analysis, and the development of a novel circular economy framework. Findings highlight responsible resource use, waste reduction, and innovation management within the sustainability context, all evaluated through the lens of the ToC. Hence, utilises network analysis to uncover key relationships, collaborations, and influential stakeholders, presenting opportunities for strategic partnerships that align with the envisioned impact of the ToC. The comprehensive framework developed herein serves as a guide for practical interventions and strategic resource management in Bozcaada, fostering circular economy principles. Stakeholders and decision-makers can leverage this research to assess and enhance urban sustainability, aligning with the Theory of Change impact, in developing countries.

OR in Heating Systems

Stream: OR in Energy

Invited session

Chair: Sandra Venghaus

1 - Planning of Power-Water-Heat Systems Using an Integrated, Extremes-Aware, Clustering-Optimization Framework

Jefferson Riera, Ricardo Pinto de Lima, Omar Knio

The rising shift towards renewable energy sources to decarbonize the power sector highlights the need to create advanced optimization tools that capture variability and complementarity of renewable resources and incorporate infrequent but critical extreme weather conditions planning models. A clustering-optimization framework is introduced to address extreme weather conditions when planning for a multi-sector (including power, water, and heat) system, aiming to mitigate the effects of detailed variability. This framework was applied to assess the financial and resilience outcomes of adding concentrated solar power (CSP) and geothermal energy into a system already utilizing wind, solar photovoltaics, and batteries. When planning for fully renewable energy systems, extreme weather conditions necessitated higher capacity investments to reduce reliance on external power sources. Whereas technologies like CSP and geothermal have been shown to lower costs across the system, the inclusion of CSP could lead to decreased reliability during extreme weather events. This underscores the importance of designing energy systems that not only embrace renewable technologies but also robustly withstand and adapt to the challenges posed by extreme weather conditions, ensuring both sustainability and reliability in the face of climate change.

2 - Integrated flexible heating and cooling under climate uncertainty in a European energy systems model

David Huckebrink, Leonie Sara Plaga

To inform the urgently needed energy transition, models are used to find the optimal design and operation strategy of future energy systems. Since the focus of studies in this field has largely been on the

power sector, synergies between coupled sectors have not been sufficiently researched. The integration of heating is important because of three reasons: First, heating is mostly fossil fuelled and offers a large decarbonisation potential. Second, decarbonisation achieved through electrification is a mix of both a burden through increased demand and a benefit through greater flexibility to the power sector. Third, heating and cooling demands depend on the weather, which is subject to uncertainty in the future. Therefore, we propose an integrated model of the European power system and heating and cooling demands that can be met flexibly while taking different climate projections into account. The methodology can be split into three steps. The first step is data clustering and merging of the European electricity transmission and generation capacities, heating and cooling demands and respective technologies and weather timeseries. Second, heat demands are used to derive aggregated buildings' multi-node representations. Finally, the model will be optimised using Backbone and decarbonisation is achieved through GHG emissions limits. The results of this work allow for the electricity and heating sector to be analysed in an integrated fashion and will be publicly available.

3 - Reduction of Fossil Fuel Usage for Hydrogen Production in District Heating Networks by Implementing PV Energy

Karina Medwenitsch, Lukas Gnam, Markus Schindler

In order to achieve the goals of the European Green Deal set by the European Commission, a reduction of the usage of fossil fuels is necessary. This also applies to the sector of district heating, where gas is still widely used, specifically in Austria. The district heating network in Neusiedl am See in the Austrian Burgenland region comprises a gas boiler, a biomass plant as well as four high-performance heat pumps, which are fueled by energy generated in the local wind park, as heat production components. Although the share of gas used for the heat production is already low with only a few per cent, depending on the current electricity prices, the gas boiler is still necessary for the operation of the district heating network. Additionally, an electrolyzer was integrated into the system in 2023 in order to use the surplus energy from the wind park for the production of hydrogen. However, when operating the district heating network most economically, the hydrogen production leads to a significant increase in the gas share, with the percentages ranging between 17 and 21 %. The objective of this work is to reduce the usage of gas in the network while also operating the electrolyzer by implementing additional energy from a hypothetical PV plant nearby. The results show that the gas share is crucially reduced to a range of 4 to 10 %.

4 - Reducing Greenhouse Gas Emissions through Strategic Subsidy Allocation for Building Heat Technologies: A bi-level Optimization Approach

Sebastian Lubjuhn, Sandra Venghaus

The global population is battling with the urgent need to transition towards sustainable and efficient energy systems. With 15% of the total emissions in Germany, the heating sector is one of the largest greenhouse gas-emitting sectors. Subsidies are key policy instruments governments employ to incentivize the adoption of such technologies. However little research has been done on optimizing these subsidies to achieve the best emission reduction on a long-term horizon. This challenge is compounded by the colliding interests of the German government, which aims to minimize total emissions through subsidy allocation, and property owners, who seek to minimize costs through investments in heating technologies. While certain heating technologies may offer short-term sustainability benefits, others hold greater potential for long-term emission savings. To address this issue, we propose a bi-level optimization model utilizing a modified grid search at the upper level and linear programming at the lower level to optimize subsidy distribution decisions. Preliminary findings indicate that subsidies targeting both heating pumps and biomass heating show promise for maximizing emission reduction. Nonetheless, it is observed that additional subsidies for biomass heating entail substantial costs relative to their marginal impact. This underscores the importance of careful subsidy allocation strategies to achieve optimal outcomes in emission reduction efforts.

Integrative Approaches in Health and Disease: From Molecular Structures to Clinical Outcomes

Stream: Computational Biology, Bioinformatics and Medicine

Invited session

Chair: Agnieszka Rybarczyk

1 - Quality assessment of 3D RNA structures using graph neural networks

Maciej Antczak, Bartosz Adamczyk, Marta Szachniuk

General quality assessment of 3D RNA structures predicted in silico is crucial to identify native or near-native 3D RNA folds. Nowadays, there are many, freely available computational methods for 3D RNA structure prediction, however without the reference - experimentally determined 3D RNA structure - it is difficult to reliably rank them in terms of practical usefulness. Here, we propose to apply graph neural networks to precisely infer the interatomic relationships commonly observed in 3D RNA structures and therefore reliably predict the quality of RNA structures. We started with the preparation of a high-quality training dataset based on experimentally determined structures retrieved from a non-redundant 3D RNA structures repository. Due to the scarcity of the available structures, we had to extend the dataset by 3D RNA models predicted using all state-of-the-art methods for 3D RNA structure prediction. We confirmed that graph NNs can harness a wide range of conformational space. We also solved the problem of variable-length 3D RNA structure representation crucial for the proper application of machine learning techniques by constructing local 3D motifs and applying an ensemble of local quality scores to assess the whole 3D RNA structure quality. A novel general quality assessment approach that does not need the reference 3D structure to reliably rank RNA 3D structures, we believe will be a breakthrough in the field of RNA structural bioinformatics.

2 - A Large Neighborhood Search Matheuristic for the Balanced Minimum Evolution Problem

Henri Dehaybe, Daniele Catanzaro, Allan Sapucaia

The Balanced Minimum Evolution Problem (BMEP) is a hard combinatorial optimization network design problem arising in the field of phylogeny estimation. In this framework, the phylogeny is represented by an unrooted binary tree where the leaves are the individuals (the taxa), and the internal nodes represent speciation events. Given a matrix of estimated distances between each pair of taxon, the aim is to reconstruct the most accurate phylogeny according to the minimum evolution principle. We propose a Large Neighborhood Search (LNS) procedure to improve locally optimal solutions initially obtained by the state-of-the-art method (FastME). This LNS procedure works by iteratively destroying a subset of the incumbent unrooted binary tree, and then reconstructs it with a matheuristic-based repair operator. Due to its local search nature, this LNS procedure provides a scalable way of obtaining more accurate phylogenies for large datasets by directly improving the solutions found by the state-of-the-art method.

3 - Identifying Key Therapeutic Targets for Treating Hyperglycemia-Induced Atherosclerosis Using a Petri Net-Based Model

Agnieszka Rybarczyk, Dorota Formanowicz, Piotr Formanowicz

Persistent high glucose levels, a hallmark of diabetes mellitus (DM), lead to widespread cellular damage. Atherosclerosis, occurring alongside glucose metabolism disturbances, significantly complicates the condition and accelerates in DM, making it critical to slow its progression. Identifying intervention targets within the complex network of molecules and processes, without disrupting essential functions, is

challenging. Here, computational testing, like in silico analysis, becomes crucial for identifying potential therapeutic targets effectively. In our study, we used a Petri net model to identify key network nodes whose blockade could impede atherosclerosis in hyperglycemia. Our findings suggest that inhibiting isoforms of protein kinase C in diabetic patients could help slow the progression of atherosclerosis. Additionally, we observed that inhibiting aldose reductase could decelerate atherosclerosis advancement and reduce PKC expression in DM. Targeting oxidative stress by inhibiting the AGE-RAGE axis emerges as a promising therapeutic strategy for managing hyperglycemia-induced atherosclerosis. While blocking NADPH oxidase, the primary enzyme responsible for generating reactive oxygen species (ROS) in blood vessels, only marginally impeded atherosclerosis development, it effectively halted the increased production of mitochondrial ROS associated with mitochondrial dysfunction. These findings lay the groundwork for more in-depth studies.

Tuesday, 12:30-14:00 - Room: 49 (building: 116)

Efficiency, equity and fairness in humanitarian operations

Stream: OR in Humanitarian Operations (HOPE)

Invited session

Chair: Zehranaz Donmez

1 - Vulnerability Based Prioritization in Disaster Response Efforts

Halenur Sahin, Feyza Sahinyazan, Irfan Mahmutogullari

Humanitarian logistics literature commonly uses Equity, Efficiency and Effectiveness (3E) objectives. The equity objective aims to minimize differences in individual treatments by assuming equal impact for everyone in a disaster. Efficiency measures aim to reduce the costs of aid programs, while effectiveness focuses on the quality of humanitarian aid, measured by factors such as response time, reduced risk, or human suffering. 3E objectives presume beneficiary homogeneity, yet it is crucial to recognize that disasters disproportionately impact socioeconomically disadvantaged individuals. Vulnerable groups—low-income, elderly, disabled, or marginalized—face distinct challenges and heightened risks in disasters. Any measure assuming homogeneous demand neglects the intersectionality of vulnerable communities. This study presents an alternative approach to prioritizing vulnerable populations in disaster response, striving for a more inclusive and compassionate disaster management strategy. To assess the performance of this approach against traditional 3E measures, we analyze the emergency assembly point allocation problem using Istanbul's neighborhood-level vulnerability and population characteristics in our computational study. Our results show that the vulnerability-based prioritization approach can single-handedly achieve more inclusive results for vulnerable populations without significantly deteriorating 3E objectives and non-vulnerable population outcomes.

2 - Efficient and equitable transportation of casualties by Online Optimization in mass casualty incidents

Fatemeh Zare Bidaki, Davood Shiri, Sibel Salman

After a mass casualty incident, numerous victims endure severe injuries with different chances of survival, requiring timely rescue operations and prioritization in transportation. We develop a Mixed-Integer Linear Programming (MILP) model for a multi-period routing and scheduling problem for a heterogeneous rescue fleet with the objective of maximizing the expected number of survivors. Recognizing the uncertainties inherent in such situations, such as fluctuations in the victim population and their conditions over time, we propose an online optimization algorithm. This allows for real-time adjustments to the rescue operations based on incoming data. Our framework favors equity in healthcare service delivery through various fairness metrics.

Validation of proposed approaches is achieved through computational tests and offline comparisons with real-world scenarios.

3 - Relief Supply Chain Planning: Fair allocation of in-kind donations in post-disaster phase

Zehranaz Donmez, Bahar Yetis Kara, Ozlem Karsu, Francisco Saldanha-da-Gama

In this paper, we study the relief logistics problem that emerges in the response phase after a disaster. We consider a case in which a set of demand nodes must be supplied with some urgent commodity over a planning horizon. The supply for this relief item is irregular and time-dependent and often not enough for the demand since, for instance, it may depend on voluntary donations. As observed in previous disasters, donations lead to a high level of uncertainty in the distribution network as the amount depends on the choice of volunteers. We assume that supply information reveals at the beginning of each period, upon processing the collected in-kind donations. This uncertainty poses a major challenge when it comes to fairly distributing the available amount. The problem of interest can be cast as a multi-period location-inventory problem and formulated using multi-stage stochastic programming. Unlike most of the existing literature, location decisions take place in each stage of the planning horizon as the information gradually reveals. The mathematical model is tested using instances built from real data available in the literature, using a set of scenario trees with different supply levels. Computational tests are made on these benchmark instances with various sizes of network and scenario trees. The results show that the new modeling framework can be extremely useful when it comes to finding fair solutions for supplying a relief item with uncertain availability.

4 - Equitable location-allocation in multistage humanitarian settings applied to Brazilian disasters

Jie Bao, Douglas Alem, Aakil Caunhye

This research develops a novel three-stage stochastic location-allocation model for a preparedness-response disaster relief problem within a scenario-based stochastic programming setting. In the mainstream academic literature, preparedness-response activities are commonly represented within a two-stage stochastic programming framework assuming there is a single moment when all uncertain parameters are revealed. Grounded on practical disaster operations, our approach considers two moments within the disaster timeline in which different related uncertain parameters are unveiled: victims' needs and donation. The main rationale is to represent practical disaster aftermath situations in which right after the disaster strikes a given region, victims' needs become known and donation campaigns start collecting relief items. The precise and available donation amount is finally revealed when the donation campaign ends and it is very much dependent on the victims' needs. In this three-stage model, the initial stage involves facility location decisions about establishing distribution centres and relief prepositioning, while the next two stages involve last-mile distribution decisions about prepositioned and donated supplies. And we fully account for deprivation costs arising from unmet victims' needs in our modelling. Our results are based on real disasters in Rio de Janeiro, Brazil.

Yifu Ding, Thomas Magnanti

Produced from renewables, green hydrogen can be used as a clean fuel in the transportation and power generation sectors. According to the International Energy Agency, the annual production of low-emission hydrogen could reach 38 million tons in 2030. However, hydrogen transportation across a large system produces significant costs and emissions, undermining its decarbonization purpose. This talk will present a supply chain optimization model that addresses variability and uncertainty in green hydrogen and ammonia production. Specifically, the optimization model will consider the production and storage of green hydrogen and ammonia and their transportation to different destinations via tube trucks, trucks, rail, or ships. The uncertainty-aware formulation will model the variability and uncertainty of renewables during hydrogen and ammonia production.

2 - Design a robust renewable electricity system for Europe considering extreme weather conditions

Xiaoming Kan

Following sustained cost reductions and rapid diffusion into the power generation mix, renewable energy technologies such as wind power and solar PV may serve as the cornerstone for the future electricity system. An electricity system dominated by wind and solar is susceptible to uncertainty in weather conditions, particularly long periods of low wind and sunlight, known as "Dunkelflaute." Previous studies investigating how to design a renewable electricity system typically employ a deterministic approach, which assumes perfect foresight about future weather conditions. In this study, we develop an adaptive robust optimization model to analyze a future renewable electricity system for Europe while considering the uncertainties in weather conditions. We analyze 40 years of historical weather data using the Finkelstein-Schafer statistical method to identify extreme weather conditions for wind and solar power. Our results show that considering "Dunkelflaute" events for the entire Europe may increase the installed generation capacity by 16% for wind power and 36% for solar PV, compared to the base case results calculated with typical weather data. Additionally, the transmission grid is more than doubled, while the hydrogen storage capacity is eight times greater than the base case. Consequently, the electricity system cost may increase by more than 20%. These results highlight the importance of accounting for weather-related uncertainties in designing future electricity systems.

3 - Uncertain Unit Commitment For The Operation Of Hybrid Power Plants Under Uncertainty

Nouha Dkhili, Vincent Leclere, Marco Marchese, Anna Robert, Vitor Luiz Pinto de Pina Ferreira

The increased deployment of renewable energies introduces intermittency in power generation that was reliably dispatched in the past. The conventional Unit Commitment problem in energy system management consists in optimizing the operation schedule of thermal units to meet the load at minimum cost and CO₂ emissions. However, Uncertain Unit Commitment (UUC) models extend this framework by integrating uncertainties stemming from generation, load fluctuations, pricing, etc. These extensions require decomposition-based computational methods to solve these problems efficiently and accurately. TotalEnergies collaborates with Ecole des Ponts (CERMICS lab) to focus on an isolated industrial energy-intensive site, initially with a known load. The energy demand must be met by internal resources: thermal generators, PV panels, and batteries. The complexity of this problem stems from the interplay of factors like storage and ramping constraints, interstage coupling, binary variables, and the intermittency of solar energy. Ensuring continuous load fulfillment remains imperative for safety and reliability. Yet, an overly cautious approach can result in high production costs and CO₂ emissions. We study the risk-neutral and risk-averse approaches via the stochastic and robust settings, respectively. By separating the information structures behind binary and continuous variables, we can decouple them in the optimization problem and use cut-generation algorithms to solve both problems.

1 - Will hydrogen remain green? Supply chain optimization for green hydrogen transportation considering production uncertainty

4 - Operational optimization of energy flows in energy-based industrial symbiosis

Daniela Guericke, Alessio Trivella, Devrim Murat Yazan

Industrial symbiosis (IS) is a concept of circular economy, where one company utilizes waste, residue, or by-products of another company to replace otherwise needed resources. Companies can also engage in energy-based IS. Here they either utilize waste energy streams directly in energy cascades, or they use waste products for fuel replacement and bioenergy production. Examples are the utilization of waste heat from industrial processes in district heating systems or the usage of industrial or urban waste for energy production. The concept of energy-based IS is often applied in so called hubs for circularity (H4C), i.e., industrial parks where co-located companies collaborate to close energy and resource loops. In this work, we present a modelling approach to optimize the operational planning of the energy flows in a H4C utilizing energy-based IS. Since the waste (energy) streams are by-products of other main production processes, they are not plannable and, therefore, uncertain and volatile. To address this uncertainty, we apply stochastic programming. We present results for a case study using industrial and public data and input from literature. In our experiments, we investigate the benefits of energy-based IS for the energy cost and energy mix of the hub.

Optimization for the Circular Economy

Stream: Circular Economy, Remanufacturing and Recycling

Invited session

Chair: *Gerardo Perez Valdes*

1 - Mixed sustainable supply chain design: a case of the recovery of end-of-life tires and batteries

Andrea Espinoza, Jeremías Vásquez, Pavlo Santander

The increasing amount of waste generated, combined with a lack of proper management, has resulted in the development of policies to encourage the recycling of end-of-life (EOL) products. Extended producer responsibility (EPR) has been one of the most common regulations, holding producers accountable for the management of the products they manufacture. End-of-life tires (ELTs) and batteries are two of the most common EOL products covered by EPR laws. Different supply chain designs have been proposed in the literature to address the treatment of both products, but they address them separately. The study presents a multi-objective optimization model for the development of an integrated supply chain considering three different objective functions to assess economic, environmental, and social perspectives. The proposed model is applied to a case study in Chile's Metropolitan Region. The e-constraint methodology yields a Pareto front used to calculate a compromise solution. The supply chain exhibits a unique distribution compared to previous mono-objective iterations, featuring a mix of different technologies installed at both the centers and reprocessing plants. The system processes 33.17% of the total available EOL products. This total fulfills the minimum requirements established by the EPR law in Chile of 3% for batteries and 25% for ELTs.

2 - Formalising e-waste Supply Chain for Sustainable Development

Sheeba Pathak, Wolfgang Garn, Christopher Turner

The e-waste management market is a major business opportunity with a projection to grow to USD 137.60 bn by 2029 being a key motivator to undertake research in this area. A formal, methodical, organised sector is essential to ensure the best possible collection of e-waste as well as its proper disposal or recycling. While the UN SDG Goal No. 12 aims for responsible production and consumption,

businesses are still looking into ways to guarantee that e-waste collection, recycling, or disposal is not an expensive endeavour. This implies that a variety of activities throughout the supply chain would be involved, not only in the collection, disposal, and recycling of e-waste, but also in the establishment of a system for its management. This paper builds on the novel Present-Unique-Repeatable-Environmentally-friendly (PURE) framework underlying the introduction of makerspaces and Centre for Refurbishment and Recycling of Electrical and Electronic Waste (CReW) & addresses quantitatively how the network flow should be to achieve sustainable development goals of minimising cost and emissions. Also generates employment opportunities while tackling health concerns for those residing within the proximity of landfills. Therefore it ensures a leaner process that can be adopted horizontally across industries while also coining electronic reverse logistics into e-waste's forward logistics as a formal supply chain design

3 - A Scenario-Based Stochastics Programming Framework to Enhance Viability: Aligning R-imperatives, Product Development, and Supply Chain Design

Sobhan Mostafayi Darmian, Juan Pablo Morande, Fabio Sgarbossa, Mohammad Fattahi

Recent research highlights that supply chains (SC) need to be resilient against disruptions and adaptable to long-term shifts in demand and supply environment. Moreover, there is a growing recognition of the need to transition towards a circular economy to protect the environment while promoting economic growth. This has led to a call for developing SCs that are sustainable, resilient, and adaptable, called viable SCs. Motivated by a manufacturing company in Norway as the case study, this study proposes a scenario-based stochastic programming framework to measure resilience and adaptability through qualitative scenarios. It also suggests integrating the core principles of the circular economy, which are called R-imperatives, into product development processes and supply chain design decisions to make SCs viable. Our results reveal the crucial role of implementing R-imperatives into the integrated PD and SC design for establishing the foundations of design for viability.

4 - Optimisation and Macroeconomic models in Circular Economy analyses

Gerardo Perez Valdes, Amira Rachah, Kirsten S. Wiebe

In this presentation, we showcase a range of projects that integrate optimization and macroeconomic modeling to explore the circular economy in Norway.

The first project focuses on utilizing input-output modeling to evaluate the impacts of building renovation policies in Oslo, with a specific emphasis on energy efficiency measures. The findings of this work have been published in peer-reviewed journals and serve as a foundation for future analyses that combine detailed technical information with macroeconomic analysis.

The second project, Synagri, employs supply-use modeling to assess the effects of biotechnology advancements in the agricultural sector and their benefits for farmers and other stakeholders near the beginning of the value chain. In particular, the project considers and models the circularity and reuse of byproducts of the animal rearing and food processing.

Lastly, the European project Treasource employs value-chain optimization in the context of recycling plastics, batteries, and bio-based streams in Northern Europe. The developed model focuses on waste generated from industrial processes and consumption, exploring its recycling potential.

All of the aforementioned projects prioritize data-driven circular economic analysis and cover diverse topics, each presenting their own unique challenges and requirements. Some of them have concluded, while others are ongoing work.

1 - Price Subsidies with or without Physical Procurement: Impact on Quality, Profits, and Welfare

Aysajan Eziz, Nagesh Gavirneni, Omkar D. Palsule-Desai

Newly introduced price subsidy programs without physical procurement have resulted in an increased (vis-à-vis the subsidy programs with physical procurement) preponderance of deliberate quality degradation for certain crops by Indian farmers. The physical procurement of the crop from farmers provides an alternate sales channel to farmers enabling the government to subdue the competition between farmers in the open market. The farmers' deliberate quality degradation may moderate the benefits of the altered competitive structure. The viability of such programs has been questioned, and policymakers are looking for guidance. Using a multi-stage incomplete information-based (Bayesian) game-theoretic model, we comprehensively characterize the farmers' strategic production and selling decisions. We demonstrate that the government price support with multiple sales channels created by physically procuring the crop improves the producer surplus when the farmers' landholdings are highly disparate and the quality-based competition is lower. A higher minimum support price (MSP), a higher landholding for a farmer producing a high-quality crop, and a lower high-quality crop price premium in the open market improve the consumer surplus, the social surplus, and the average quality of the crops supplied by farmers when the government does not procure the crop physically v/s when it does. We provide guidance to the government exercising caution in selecting MSP and farmer subsidy program.

2 - Strategic Decisions and Sustainability in Competitive Agricultural Supply Chains: A Triple Bottom Line Perspective

Pritha Dutta, Deniz Besik, Sara Saberi, Rodrigo Mercado Fernandez

This paper presents a mathematical modeling framework of a competitive multiperiod agricultural supply chain network under the triple bottom line sustainability, comprising financial, environmental, and social aspects. In our competitive supply chain modeling framework, agri-food firms strategically determine the flows of agricultural products to demand markets, the scale of farmland used for sustainable and conventional farming practices, and the allocation of labor for both sustainable and conventional farming practices. Profits determine the financial sustainability component, while environmental sustainability is assessed based on the total greenhouse gas emissions generated and the amount of water consumed. Social sustainability is measured through a social benefit function that considers the labor employed for both sustainable and conventional farming practices, as well as agri-food firms' overall economic contribution through agricultural production in the regions. The competition between agri-food firms is studied through game theory, where the governing Generalized Nash equilibrium conditions correspond to a variational inequality problem. We use the Euler method as the algorithm to analyze a numerical study focusing on avocado supply chains. We draw attention to the potential impacts of climate change and deforestation in our numerical study. Given the trade-offs, our findings highlight the importance of achieving the triple bottom line.

3 - Battling Waste and Empowering Growers with Ugly Veg: The Role of Contracts

Behzad Hezarkhani, Guven Demirel, Yann Bouchery

The production process of fruit and vegetable often generates produce that does not conform to the aesthetic standards established by the retail sector. The so called "ugly veg" is a major contributors to global

food waste. In this paper, We examine the capability of agri-food supply chains to incorporate ugly veg to reduce food waste and financially empowering the growers who are often the weakest link. We model the interactions between the players in the chain and compare and contrast the common spot contracts with the so called "whole-crop contracts". We examine the players' incentives to up-cycling the ugly veg, and assess the potential to reducing waste and protecting growers against low wholesale prices.

1 - A survey on ILP formulations for the kidney exchange problem

Mathijs Barkel, Rachael Colley, Maxence Delorme, David Manlove, William Pettersson

Kidney exchange programs facilitate life-saving transplants by allowing patients with willing but incompatible donors to exchange their donors either through cycles, or through chains initiated by non-directed donors. In each matching run, one must identify a maximum weight packing of cardinality-constrained vertex-disjoint cycles and chains on a compatibility graph. This computational problem, known as the Kidney Exchange Problem (KEP), is both theoretically and empirically hard.

We conduct a survey of existing integer linear programming formulations and associated model-related enhancements for the KEP, extending upon prior work by including the most recent advances. Our key contribution lies in addressing a gap in the literature: whereas models for only cycles have been extensively studied, models for both cycles and chains have received less attention. We demonstrate that all cycle models can be adapted to model chains, thereby enabling a comprehensive approach to modelling cycles and chains by merging any cycle model with any chain model. Furthermore, we explore alternative strategies, such as modelling cycles and chains concurrently using a shared set of variables.

Additionally, we conduct extensive computational experiments on generated instances to evaluate and compare the performance of the different model combinations for varying instance parameters, providing valuable insights for practitioners and researchers alike in effectively addressing the KEP.

2 - Uncertainty-affected graph problems solution through Bulk Optimization

Paolo Paronuzzi, Christoph Buchheim, Enrico Malaguti, Michele Monaci

This work explores graph optimization problems, focusing on bulk optimization setting where potential link failures in different scenarios introduce uncertainty. Bulk optimization, a recently introduced problem class in the literature, recognizes that in many practical cases, uncertainty affects only a small portion of the system. This contrasts with robust optimization, often considered overly conservative. Accordingly, the number of scenarios and the number of edges per scenario, although not necessarily low, are finite and limited. Given a graph and a cost for each edge, our goal is to activate a subset of edges of minimum cost, ensuring that the resultant graph presents some desired structure (i.e., a perfect matching or a spanning tree) in each scenario. Our study develops a Benders' decomposition approach where the master problem encapsulates variables determining which links to activate, while the subproblems verify the feasibility of the master solution in each scenario. The transformation of the subproblems into an efficiently

solvable flow problems enhances computational tractability. Although the bulk optimization paradigm has been studied for what concerns its theoretical properties, and some approximation algorithms have been proposed, we are not aware of any computational approach. The proposed approach demonstrates promising results and applicability, offering a robust and scalable solution algorithm for graph problems in the presence of uncertainty.

3 - Lower and upper bounds for resources allocation in lightpath communication networks

Enrico Malaguti, Francesco Cavaliere, Federico Michelotto, Michele Monaci, Daniele Vigo

We consider the problem of allocating wavelengths of an optical network in order to serve a set of connection requests. In order to provide a robust allocation, communication must be ensured even in case of failure of some link, which is obtained by defining, for each connection request, two disjoint paths in the network. Each connection uses its working path by default, and is rerouted to its unique recovery path in case the working path is unavailable. As uniquely assigning both paths to a single connection may be highly inefficient, we adopt a shared protection policy, in which the same wavelength and path can be shared among different connections, provided that no collision arises. We discuss alternative relaxations for the problem based on Mixed-Integer Linear Programming formulations, and introduce a metaheuristic algorithm based on the Ruin-and-Recreate paradigm. Computational experiments on realistic data show that our algorithms are able to produce feasible solutions with tight optimality gap.

1 - Enhancing Efficiency and Sustainability through Reconfigurable Delivery Systems

Fatima Ezzahra Achamrah, Sabine Limbourg

Funded by the Grantham Centre for Sustainable Futures, this research explores the development of a dynamic system for urban last-mile delivery, aimed at enhancing efficiency, resilience, and sustainability in urban logistics. Focusing on integrating real-time traffic data and predictive analytics, the study extends a previous work on a consolidation-based multi-modal delivery model, grounded in Life Cycle Assessment methodology.

Central to this research is the incorporation of real-time traffic data from platforms like Waze. This data is crucial for dynamically reconfiguring delivery routes in response to changing traffic conditions, thereby maintaining operational efficiency and resilience. Alongside, predictive analytics, utilising machine learning algorithms and demand forecasting models, plays a significant role. Focused on Sheffield area, the study also leverages data from platforms like UK Open Data for informed and automated territory reconfiguration processes. We further use Global Mapper software and clustering algorithms for dynamic adjustment of delivery territories.

The implementation strategy included a comprehensive simulation phase using AnyLogic. This phase was instrumental in modelling urban traffic and delivery scenarios, allowing for an effective comparison of the dynamic system against traditional static models. Key performance indicators such as operational costs, delivery times, and environmental impacts were analysed, providing valuable insights.

2 - A Metaheuristic for the Optimal Placement of EV Charging Stations in an Urban Environment

Bryan Coulier, Hatice Çalık, Thijs Becker, Greet Vanden Bergh

In response to global environmental concerns and policy initiatives, the automotive industry is currently undergoing a significant transformation towards sustainable transportation. As EVs become a major component of the transition to a greener, more electrified future, governments are investing heavily in charging infrastructure. The rapid rise of EV adoption poses significant challenges to conventional power grids. Intelligent solutions are necessary in order to ensure reliable and efficient charging infrastructure.

Current studies concerning EV charging infrastructure often overlook the underlying power distribution network and the accessibility of charging stations for EV users. The majority of these studies are small in scale, employing metaheuristics without validating their results using exact solutions. Moreover, researchers have predominantly focused on fast chargers, while slow chargers play an equally crucial role in urban settings.

In an effort to address these significant gaps, our research focuses on the placement of slow charging stations in urban areas while taking into account (i) the distribution network, (ii) customer demand, and (iii) accessibility. We propose a novel Mixed-Integer Linear Programming (MILP) model to determine the optimal placement, quantity, and type of charging stations. To enhance scalability and computational speed, we also introduce a multi-stage metaheuristic for solving large-scale instances by decomposing the grid network.

3 - Improving Route Planning of Electric Vehicles by Considering Road Gradients and Regenerative Braking

Sina Rastani, Merve Keskin, Tugce Yuksel, Bülent Çatay

With the increasing greenhouse gas emissions, the use of electric vehicles (EVs) in logistics has increased. In contrast to conventional vehicles, EVs use batteries to store energy, and they often stop at stations to recharge. The energy consumed per unit distance traveled depends on several factors including vehicle load, speed, and road gradient. Traversing an arc with a positive gradient requires more energy compared to an arc on a flat network. This is further amplified when the EV carries a heavy load while moving uphill. Conversely, if the driver presses the brake pedal to maintain a constant speed while moving downhill, it can regain energy through regenerative braking technology. The impact of road gradients and regenerative braking may be significant for companies that carry heavy loads in hilly regions. Therefore, an approach that incorporates both cargo weight and road network terrain may improve the route planning of EVs. With this aim, this study addresses an extension of the Electric Vehicle Routing Problem with Time Windows considering a comprehensive energy consumption function that incorporates the cargo load, road gradient, and regenerative braking. We formulate the problem as a mixed integer linear program, solve small-size instances with Gurobi, and develop a Large Neighborhood Search to tackle the large-size instances. Numerical results show that considering the road gradient along with the cargo weight can significantly influence the routing decisions.

Mathematical Optimization for Trustworthy Machine Learning

Stream: Mathematical Optimization for XAI

Invited session

Chair: *Connor Lawless*

1 - Slowly varying regression under sparsity

Vassilis Digalakis

I will present the framework of slowly varying regression under sparsity, allowing sparse regression models to exhibit slow and sparse variations, through an application in energy consumption prediction. First, I will formulate the problem of parameter estimation as a mixed-integer optimization problem; then, I will demonstrate that it can be precisely reformulated as a binary convex optimization problem through a novel relaxation technique, convexifying the non-convex objective function while matching the original objective on all feasible binary points. I will develop a highly optimized implementation of a cutting plant-type algorithm, a fast regularization-based heuristic method that guarantees a feasible solution, and a practical hyperparameter tuning procedure relying on binary search that, under certain assumptions, is guaranteed to recover the true model parameters.

2 - Improving pricing strategies on a branch-and-price algorithm for the hyper-rectangular clustering problem with axis-parallel clusters

Diego Delle Donne, Javier Marenco, Eduardo Moreno

Given a set of points in the space of an arbitrary dimension, the hyper-rectangular clustering problem with axis-parallel clusters (HRC-AP) consists in grouping the points into clusters, each cluster being determined by a hyper-rectangle in the corresponding space. HRC-AP has been proposed as a model for explainable clustering, as it is straightforward to describe the clusters by the bounds defining each hyper-rectangle: if each coordinate corresponds to a relevant parameter in the application generating the points, then a cluster is specified by its bounds on each parameter. A variant of HRC-AP considering the existence of outliers (called HRC-APO), allows a certain number of points to be discarded and not included in any cluster. In previous works, we explored integer programming techniques for HRC-APO proposing several formulations and algorithms. We showed that extended formulations (solved via branch-and-price) outperformed classical compact formulations. Nevertheless, these techniques fall short as soon as the number of points to be clustered is increased to medium-sized real-life instances. In this work we propose an innovative strategy to solve the pricing problem by modeling it as a flow problem. This allows us to develop a polynomial-time routine for the pricing, qualitatively improving the performance of previous approaches. We compare the efficiency of the new method against the existing ones by providing an exhaustive computational experimentation.

3 - An Optimization-Based Order-and-Cut Approach for Fair Clustering of Data Sets

Hrayer Aprahamian

Machine learning algorithms have been increasingly integrated into applications that significantly affect human lives. This has spurred interest in designing algorithms that train machine learning models to minimize the training error while imposing a certain level of fairness. In this paper, we consider the problem of fair clustering of datasets. In particular, given a set of items, each associated with a vector of non-sensitive attribute values and a categorical sensitive attribute, our goal is to find a clustering of the items that minimizes the loss (i.e., the clustering objective) function while imposing fairness measured by Rényi correlation. We propose an efficient and scalable in-processing algorithm, driven by findings from the field of combinatorial optimization, that heuristically solves the underlying optimization problem and allows for regulating the trade-off between clustering quality and fairness. The approach does not restrict the analysis to a specific loss function but instead considers a more general form that satisfies certain properties. This broadens the scope of the algorithm's applicability. We demonstrate the effectiveness of the algorithm for the specific case of k-means clustering, as it is one of the most extensively studied and widely adopted clustering schemes. Our numerical experiments reveal that the proposed algorithm outperforms existing methods by providing a more effective mechanism to regulate the trade-off between loss and fairness.

4 - Fair Minimum Representation Clustering

Connor Lawless

Clustering is an unsupervised learning task that aims to partition data into a set of clusters. In many applications, these clusters correspond to real-world constructs (e.g. electoral districts) whose benefit can only be attained by groups when they reach a minimum level of representation (e.g. 50% to elect their desired candidate). This paper considers the problem of performing k-means clustering while ensuring groups (e.g. demographic groups) have that minimum level of representation in a specified number of clusters. We show that the popular k-means algorithm, Lloyd's algorithm, can result in unfair outcomes where certain groups lack sufficient representation past the minimum threshold in a proportional number of clusters. We formulate the problem through a mixed-integer optimization framework and present a variant of Lloyd's algorithm, called MiniReL, that directly incorporates the fairness constraints. We show that incorporating the fairness criteria leads to a NP-Hard sub-problem within Lloyd's algorithm, but we provide computational approaches that make the problem tractable for even large datasets. Numerical results show that the approach is able to create fairer clusters with practically no increase in the k-means clustering cost across standard benchmark datasets.

1 - Geometry and deep learning-based methods comparison for segmentation of trees in aerial laser scan point clouds

Povilas Treigys, Kasparas Karlauskas

Laser scanning technology has facilitated advanced analysis of complex outdoor environments by capturing 3D point clouds. Identifying points within a point cloud corresponding to individual objects of a particular class, semantic instance segmentation is of great relevance in numerous fields. In the context of forest point clouds, in particular, semantic instance segmentation proves valuable for forestry applications such as tree inventORIZATION and infrastructure contexts such as transmission line corridor surveys, where the positioning of trees is used for safety considerations. While recent developments in deep learning algorithms for point cloud processing have yielded solutions for semantic instance segmentation in terrestrial laser scans of forests, applying such methods to lower spatial resolution aerial laser scans still needs to be explored. Compared to their terrestrial counterparts, aerial laser scans present an attractive prospect for large-scale forest analysis. This paper introduces a benchmark dataset for forest semantic instance segmentation created from publicly available aerial laser scans. The dataset is an evaluation platform for standard geometry-based classical tree instance segmentation algorithms. Additionally, it is used to evaluate a deep learning model for tree instance segmentation. A comparison between the different methods is made in the context of aerial laser scans of forests.

2 - The shortest path problem with path constraints

Nan Xu, Zhang Miaomiao, Yicong Qin, Hao Zhang

Motivated by the practical aircraft routing problem in civil flight planning, we consider a variant of the shortest path problem with inclusionary and exclusionary constraints, specifying whether node Y must or must not be visited after node X is visited. The problem is defined on a directed graph G, with a source node S and a sink node T. We introduce an algorithm that generates an augmented graph G' from the original

graph G , ensuring compliance with the inclusionary and exclusionary constraints. This transformation reduces the constrained shortest path problem in G to a classic shortest path problem in the augmented graph G' . For each inclusionary constraint, we modify the original graph to ensure that all paths from X to T pass through Y . For each exclusionary constraint, we modify the original graph so that all paths from X to Y are redirected to a duplicate node Y' , which has no outgoing arcs, ensuring that no path extended from X to T through Y/Y' . It needs to be proved that: (1) There are no paths violating the constraints in G' ; (2) For each valid path in G , there exists a corresponding path in G' ; and (3) For each path in G' , there is a corresponding path in G . We demonstrate the algorithm's validity through proofs by contradiction. Numerical experiments demonstrate the efficiency of our algorithm. Furthermore, the algorithm has been successfully integrated into our flight planning system, indicating its practical utility.

3 - A framework for modelling view change in Byzantine fault-tolerance network

Yifei Xie, Btissam Er-Rahmadi, Xiao Chen, Tiejun Ma, Jane Hillston

In the rapidly evolving field of machine learning, the increasing complexity of models necessitates larger datasets and greater computational resources. This demand for scalability and enhanced computational capabilities has driven the study of distributed optimization to the forefront. Byzantine fault-tolerance (BFT) consensus is a fundamental building block of distributed systems. BFT is the property of a system that can resist the class of failures which can continue operating even if some of the nodes fail or act maliciously, thanks to the capacity to prevent the no more than one third adversaries from gaining a consensus and the mechanism of view changes for replacing faulty nodes. Our research introduces a novel mathematical programming framework aimed at optimizing the performance of BFT algorithms. Our approach is twofold: firstly, we optimize node network distribution strategies to maximize throughput; secondly, we investigate mechanisms for selecting backup nodes to replace the leader during view change phases when failure occurs. To validate our framework, we conducted experiments on a real-world testbed. The results demonstrate significant improvements in BFT algorithm performance, showcasing our method's potential in optimizing throughput and ensuring robust fault tolerance during view changes. This study contributes to the development of more resilient and efficient distributed systems, supporting the growing demands of machine learning applications.

4 - Civil aviation route-planning method based on improved restricted searching area algorithm

Zhang Miaomiao, Nan Xu

In order to address the large calculation scale and slow route-planning speed problems caused by the large global aviation network and complicated restrictions, this paper proposed an improved algorithm for route-planning within hybrid restricted searching area. Firstly, a machine learning algorithm was used to optimize the major axis parameter of the ellipse in the ellipse restricted searching area algorithm by analyzing the historical flight plan data. Then, based on the rectangle restricted searching area algorithm and the ellipse restricted searching area algorithm, the proposed algorithm considered restrictions on the search direction to further reduce the search scale and improve the search efficiency. Experiments show that compared with ellipse restricted searching area algorithm, the hybrid restricted searching area algorithm reduces the search size by about 50% and the total execution time by 34% on average, which verifies the effectiveness of the method.

Exact Algorithms and Formulations for Network Optimization Problems

Stream: Combinatorial Optimization

Invited session

Chair: *Ivana Ljubic*

Chair: *Martina Cerulli*

1 - Anonymizing networks via mathematical programming

Carmine Sorgente, Raffaele Cerulli, Ivana Ljubic

Social network data sets are often published and used for analysis purposes in many application domains. This may raise privacy issues, as simply hiding the identity of the users does not prevent an adversary from tracing back to the real-world entities associated with certain nodes of the network having sufficiently distinguishable features from others. To protect individuals' privacy, networks are commonly anonymized before publication. In this context, the k -degree anonymization problem, originally introduced by Liu and Terzi in 2008, aims to identify the smallest set of modifications of the edge set of a network needed to make it k -degree anonymous, meaning that each user of the anonymized network will have the same number of connections as at least other $k-1$ users. In such a definition, different k values reflect different privacy requirements w.r.t. the vertex degree feature. This work addresses different settings of the problem allowing edge insertions and/or deletions. We compare different families of integer linear programming formulations of the problem on benchmark social network instances and additionally derive some properties and valid inequalities that we exploit in the solution process.

2 - Mixed-integer linear programming formulations and column generation algorithms for the Minimum Normalized Cuts problem on networks

Diego Ponce, Justo Puerto, Francisco Temprano Garcia

The normalized cut function in networks was introduced by Shi and Malik in 2000 to solve some issues concerning the interpretability of the minimum cut problem, which is a classical problem in graph theory whose aim is to provide the bipartition that minimizes the number of edges between nodes from different subsets, applied to partitioning and districting problems. The minimum k -way normalized cut problem (MkWNCP) tries to minimize the external edge density of each subset of a k -partition, also considering the number of internal edges. We develop several reformulations using mathematical programming tools to exactly obtain the minimum k -way normalized cut of a graph. This is a challenging task since the normalized cut function is non-linear because it is defined by the ratio of two linear functions of integer variables. We also propose a branch-and-price procedure for the MkWNCP which scales better than the compact formulations. Extensive computational experiments assess the usefulness of these methods to solve the k -way normalized cut problem on large graphs and random graphs. In addition, all methods have been analyzed and studied in order to try to improve them as much as possible.

3 - Estimating Optimal Split Delivery Vehicle Routing Problem Solution Values

Shuhan Kou, Bruce Golden, Luca Bertazzi

Motivated by Basel and Willemain's (2001) work on estimating optimal tour lengths in the Traveling Salesman Problem (TSP), we identify an intrinsic relationship between the distribution of the feasible solution space and the optimal solution value in combinatorial optimization problems. Our goal is to use regression modeling to estimate optimal solution values. We begin with a model that uses standard deviation as a predictor and we explain why this makes sense. We study TSP instance sets, both Euclidean and non-Euclidean. Next, we add the mean and the minimum in order to obtain very high quality results. We extend our experiments to include more than 10,000 vehicle routing problem (VRP) instances. Again, we obtain excellent results. Finally,

we focus on the more difficult Split Delivery Vehicle Routing Problem (SDVRP) by combining the mean and standard deviation predictors with two topological features. In testing on 95 diverse benchmark instances from the literature, our regression model successfully estimates the optimal SDVRP solution value to within about 3%, on average.

4 - Exact approaches for the colorful components problems

Martina Cerulli, Claudia Archetti, Carmine Sorgente

Given a vertex-colored graph G , any connected component of G is said to be colorful if all its vertices have different colors. We address three problems related to these particular components of a graph, motivated by comparative genomics: the Colorful Components (CC), the Maximum Edges in transitive Closure (MEC), and the Minimum Colorful Components (MCC) problems. In social networks, where nodes represent individuals and edges represent connections, all three problems can be used to determine the most influential connections linking distinct (colorful) and cohesive (connected) communities. By solving the CC problem, the risk of echo chambers is mitigated. Addressing the MEC problem means promoting the propagation of information through the community. Instead, the MCC problem helps prevent the isolation of users within small disconnected groups. When instead considering cyberspace networks of devices with various types of connections (e.g., permissions, data flow), identifying a subset of edges to remove while ensuring that the network remains in connected colorful components helps optimize the network's resilience to cyber threats. We formulate the three problems as integer nonlinear programs, linearize them and propose families of valid inequalities. Furthermore, we provide bounds on the maximum number of colorful components at optimality and exploit them to reduce the size of the models. Benchmark instances are tested to evaluate the performances of the proposed models.

1 - Integrating Machine Learning with GAMSPy

Hamdi Burak Usul

GAMSPy is a powerful mathematical optimization package which integrates Python's flexibility with GAMS's modeling performance. This combination opens doors to previously challenging applications, notably in bridging the worlds of machine learning (ML) and mathematical modeling. While GAMS excels in indexed algebra, ML predominantly relies on matrix operations. To enable applications in ML, our work introduces essential ML operations such as matrix multiplications, transpositions, and norms into GAMSPy. In this talk, we showcase the use of these additions by generating adversarial images for an optical character recognition network using GAMSPy. We highlight GAMSPy's versatility and its potential to be used in ML research and development. We delve into future prospects, show how GAMSPy's approach differs from existing alternatives and discuss innovative methods where mathematical modeling intersects with machine learning.

2 - Introducing the new Object-Oriented Xpress Solver API

Adam Ferreira Da Costa

A fast, scalable, and easy-to-use API is an essential component when working with commercial high-end optimization solvers. FICO Xpress has been offering Solver APIs for more than two decades for an ever-growing set of programming languages (C, C++, Java, C#, Python, R).

The new FICO Xpress Solver API for Java and C# is designed as an object-based layer ensuring a memory-efficient and reliable experience to the user. With the new API, the use of Solver features such as callbacks becomes easier, and it gives access to the full set of problem types available with Xpress Solver.

Among the key features of the new Xpress Solver API are the ability to use modern programming concepts such as Collections, Streams, Lambdas, and operator overloading to build expressions and constraints.

The new Solver API offers seamless integration with the Solver and access to cutting-edge features, and we observed model building times speedup by a factor of 8 on models with several millions of variables and constraints compared to previous APIs.

In this talk, we focus on design and architecture challenges when implementing such a new API layer. Furthermore, we will cover new features available in the augmented API, as well as examples and guidelines how to implement optimization models in object-oriented languages.

3 - Hexaly Studio: a no-code platform for mathematical optimization

Thierry Benoist, Frédéric Gardi

Hexaly Optimizer is a new kind of global optimization solver. Its modeling interface is nonlinear and set-oriented. It also supports user-coded functions, thus enabling black-box optimization and, more particularly, simulation optimization. In a sense, Hexaly APIs unify modeling concepts from mixed-linear programming, nonlinear programming, and constraint programming. Regarding performance benchmarks, Hexaly distinguishes itself against the leading solvers in the market, like Gurobi, IBM Cplex, and Google OR Tools, by delivering fast and scalable solutions to problems in the spaces of Supply Chain and Workforce Management like Routing, Scheduling, Packing, Clustering, and Location. For example, on notoriously hard problems like the Pickup and Delivery Problem with Time Windows or Flexible Job Shop Scheduling with Setup Times, Hexaly delivers solutions with a gap to the best solutions known in the literature smaller than 1% in a few minutes of running times on a basic computer. In addition to the Optimizer, we provide an innovative development platform called Hexaly Studio to model and solve rich Vehicle Routing and Job Shop Scheduling problems in a no-code fashion. The user can define its problem and data, run the Optimizer, visualize the solutions and key metrics through dashboards, and deploy the resulting app in the cloud - without coding. This web-based platform is particularly interesting for educational purposes; it is free for faculty and students.

4 - Recent Modeling and Solver Improvements in MATLAB

Paul Kerr-Delworth

The problem-based workflow is now an established interface making it much easier to model and solve optimization problems in MATLAB. Two new improvements to the problem-based workflow will be presented. First, techniques for enhanced analysis of problems will be outlined, allowing for significant performance gains on certain problems. Next, a new graphical interface for problem-based modeling in MATLAB will be introduced. Usage of the problem-based workflow for industrial applications will be illustrated with an example. Finally, key improvements to the linear, mixed integer and least squares MATLAB optimization solvers will also be shown.

1 - A distributionally robust optimisation approach to fair credit scoring

Pablo Casas, Huan Yu, Christophe Mues

Optimization under uncertainty has been a topic of large debate in Operations research (OR) and Machine Learning (ML) communities for a long time. Recently, many authors have turned to distributional robust optimization (DRO) in search of a solution; however, fewer studies have focused on enhancing fairness under uncertainty. This is of great interest in those applications of ML that can have a direct damaging impact on the population, credit scoring (CS) being one of the most potentially damaging fields according to regulatory bodies.

The paper presented explores the effects of using a DRO-based logistic regression (LR), one of the most commonly used classifiers in CS, across multiple CS datasets. This study will show how robustness has a greater impact on fairness than the fairness constraint, and that the impact on performance is negligible and, in some datasets, positive. We will also provide an empirical analysis of the effect of the different hyperparameters that are unique to DRO-based LR. Furthermore, we will argue that the level of robustness narrows the dispersion of the probability of default distribution and that the parameters in charge of the ground metric have an unnoticeable impact. On a side note, we suggest traditional fairness metrics used in credit scoring are not best suited for the task.

2 - Advancing NLP classification with disentangled embeddings: a post-processing approach to separate style from content

Nico Hambauer, Michelle Fribance, Patrick Zschech, Mathias Kraus

In the field of natural language processing (NLP), identifying cheap talk remains a challenge. Boiling down the sole content from stylized text is one approach to tackle this problem. Therefore, this study translates a recent approach known as PISCO from the computer vision (CV) field into the NLP field. This method post-processes and thereby disentangles embeddings into distinct style and content latent vector coordinates. We then isolating the chunk of neurons that only encodes the content of a text and further use this information for a classification head. Thereby, we improve the objectivity of NLP applications by removing the confounding influence of stylistic variations. With a focus on financial disclosure analysis, we aim to improve the predictive quality of sentiment and specificity downstream classification tasks. We demonstrate the technique's applicability by applying this method upfront these final classification tasks. Our initial findings suggest a promising enhancement in predictive performance for both downstream tasks. This demonstrates the potential of disentangled embeddings as a novel intermediary step towards improving NLP classification tasks. Our advances enable more accurate and evidence-based decision-making and insight generation, contributing to a more reliable and, to a certain extent, interpretable use of recent rapid advances in NLP models.

3 - Using integer programming, Markov logic networks and inference to help find missing shareholders in social networks for a New Zealand Māori indigenous incorporation

Andrew J Mason, Karl Zhu, Anthony Downward

Parinihi ki Waitotara (PkW) is a New Zealand indigenous organisation lead by Māori that manages land and other assets on behalf of thousands of shareholders. Many of these shareholders are "lost" in the sense that PkW has no contact details for them. As a consequence, PkW has millions of dollars of dividends waiting to be paid if these shareholders can be found. We have developed a system to collect public social network data and search this for the missing PkW shareholders. This involves solving the entity resolution problem to determine whether multiple document records refer to the same person or people. Traditional entity resolution approaches treat all matching decisions independently and only compare attribute similarities between reference pairs. However, this independence assumption omits valuable relational information in situations where the references describe a rich network of relationships between people. Collective entity resolution - where entities are resolved jointly - incorporates this previously

ignored information and can predict matches with greater accuracy. We use Markov logic networks to convert our domain knowledge and evidence data into a Markov network. Prediction is made by performing most probable explanation (MPE) inference on the network using integer programming formulations and a mixed IP solver. We report experiments that demonstrate how our collective entity resolution approach is able to resolve complex relational information.

4 - Energy-aware robotic multi-sided assembly line balancing problem

Abdolreza Roshani

Multi-sided assembly line balancing problems typically arise in plants producing large-sized, high-volume products such as automobiles. The difference between these assembly lines and traditional ones lies in the ability to install multiple single stations at each position along the line, enabling operators (whether workers or robots) to simultaneously perform various tasks on the same product. This paper addresses the robotic multi-sided assembly line balancing problem. Here, it is assumed that robots can be selected from a set of candidate models differing in speed and energy efficiency. Consequently, they can execute assembly tasks at varying speeds while consuming different levels of energy. The objective is to allocate robots to workstations and tasks to minimize the total cost of installing a new assembly line for a given cycle time, encompassing fixed robot costs, workstation installation costs, and energy costs. To tackle this optimization problem, a mixed-integer programming formulation is proposed. Given the problem's NP-hard nature, a metaheuristic algorithm based on the variable neighbourhood search approach is developed to address real-size instances. Computational experiments are conducted to evaluate the performance of both the proposed model and the heuristic.

Chair: *Cesare Molinari*

1 - Zeroth-order implementation of the regularized Newton method with lazy approximated Hessians

Geovani Grapiglia

In this work, we develop a zeroth-order (derivative-free) implementation of the Cubically regularized Newton method for solving general non-convex optimization problems. Specifically, we consider the class of unconstrained problems whose the objective function is twice continuously differentiable with Lipschitz continuous Hessians. The proposed method employs finite difference approximations of gradient vectors and Hessian matrices. We use a special adaptive search procedure in our algorithms, which simultaneously fits both the regularization parameters of the models and the stepsizes of the finite difference approximations. Thanks to this procedure our scheme do not require the knowledge of the actual Lipschitz constants. Additionally, we equip our algorithm with the lazy Hessian update, meaning that the method reuse a previously computed Hessian approximation matrix for several iterations. In terms of worst-case complexity, we prove that the proposed method is able to find an ϵ -approximate stationary point using at most $O(n^{3/2} \epsilon^{-3/2})$ function evaluations, where n is the dimension of the problem. This complexity bound improve existing bounds in terms of the joint dependence on n and ϵ for derivative-free methods applied to the minimization of functions with Lipschitz continuous Hessians. Illustrative numerical results confirm our theoretical findings.

2 - Accelerating Randomized Adaptive Subspace Trust-Region Derivative-Free Algorithms

Stefan M. Wild, Kwassi Joseph Dzahini, Xiaoqian Liu

This talk presents an algorithm for solving deterministic derivative-free optimization problems with thousands of decision variables. We employ a randomized dimension reduction technique based on Johnson-Lindenstrauss transforms and the trust-region framework of Cartis and Roberts. A key ingredient in our work is to extend the affine space within which the algorithm operates to include information learned in the course of the optimization. By adapting this space and judiciously using information gained in the course of the optimization, we obtain significant performance benefits on a class of large-scale test problems without sacrificing convergence guarantees.

3 - An Optimal Structured Zeroth-order Algorithm for Non-smooth Optimization

Cesare Molinari

Finite-difference methods are a class of algorithms designed to solve black-box optimization problems by approximating a gradient of the target function on a set of directions. In black-box optimization, the non-smooth setting is particularly relevant since, in practice, differentiability and smoothness assumptions cannot be verified. To cope with nonsmoothness, several authors use a smooth approximation of the target function and show that finite difference methods approximate its gradient. Recently, it has been proved that imposing a structure in the directions allows improving performance. However, only the smooth setting was considered. To close this gap, we introduce and analyze O-ZD, the first structured finite-difference algorithm for non-smooth black-box optimization. Our method exploits a smooth approximation of the target function and we prove that it approximates its gradient on a subset of random orthogonal directions. We analyze the convergence of O-ZD under different assumptions. For non-smooth convex functions, we obtain the optimal complexity. In the non-smooth non-convex setting, we characterize the number of iterations needed to bound the expected norm of the smoothed gradient. For smooth functions, our analysis recovers existing results for structured zeroth-order methods for the convex case and extends them to the non-convex setting. We conclude with numerical simulations, observing that our algorithm has very good practical performance.

4 - Stochastic derivative-free optimization algorithms using random subspace strategies

Kwassi Joseph Dzahini, Stefan M. Wild

We propose trust-region and direct-search frameworks for large-scale stochastic derivative-free optimization by introducing the STARS and StoDARS algorithms. While STARS achieves scalability by minimizing random models that approximate the objective in low-dimensional affine subspaces thus significantly reducing per-iteration costs in terms of function evaluations, these goals are achieved by StoDARS through the exploration of the decision space by means of poll directions generated in random subspaces. These subspaces and their dimension are chosen via Johnson-Lindenstrauss transforms such as those obtained from Haar-distributed orthogonal random matrices. The quality of the subspaces and sets of poll directions, as well as the accuracies of estimates and models used by the algorithms are required to hold with sufficiently high, but fixed, probabilities. Convergence and complexity results are obtained for both methods using martingale theory. In particular, by leveraging the ability of StoDARS to generate a dense set of poll directions, its almost sure convergence to Clarke stationary points is established. Moreover, the analysis of second-order behavior of the well-known mesh adaptive direct-search algorithms using a second-order-like extension of the Rademacher's theorem-based definition of the Clarke subdifferential (so-called generalized Hessian) is extended to the StoDARS framework, making it the first in a stochastic direct-search setting to the best of our knowledge.

Optimal control and resilience

Stream: Optimal Control Theory and Applications
Invited session

Chair: Stefan Wrzaczek

1 - Open-loop production control under stochastic conditions and environmental considerations

Konstantin Kogan, Dmitry Tsadikovich, Matan Shnaiderman, Beatrice Venturi

We consider a manufacturer that produces in response to a stochastic demand and emits pollution during the production process. Industrial pollutants released into the air are characterized by spatial variability and heterogeneity, and the precision of instruments for measuring stochastic pollution stocks varies widely across pollutants. Consequently, commitment (open-loop) strategies to control production and associated emissions are considered more practical than contingent (feedback) approaches when manufacturers are concerned about environmental consequences. In this paper, we derive an optimal, open-loop control policy over an infinite time horizon and show a condition that ensures that such a policy induces asymptotic convergence of expected inventory stock and pollution stock trajectories to unique steady states. Moreover, we find that the variance in the pollution stock also converges asymptotically to a unique steady state, which is critical for prevention of irreversible environmental consequences. We show that environmental uncertainty affects inventories, leading in the long run to lower expected steady-state inventory stocks. We compare feedback and open-loop production policies and show that though there are losses associated with the inability to track inventory and pollution stocks accurately and thus applying the open-loop control instead of feedback, the expected long-term inventory and pollution stocks are not affected.

2 - Offshoring and reshoring under social and economic uncertainty

Maddalena Muttoni, Alessandra Buratto

This study examines a firm adopting offshoring, the strategic relocation of business processes abroad. Motivated by cost benefits like cheaper labor and regulatory advantages, offshoring may enhance competitiveness and market access. However, in today's dynamic market, the strategic advantage of offshoring can quickly transform into a liability for firms. As consumers grow more discerning and socially conscious, factors like the MADE IN effect (the preference/aversion toward products based on their country of origin) alongside rising ethical concerns about labor exploitation and environmental sustainability, may challenge the efficacy of offshoring. Moreover, unforeseen circumstances such as war, pandemics, or social unrest can disrupt operations abroad, prompting companies to reassess their production strategy. Given these factors, we consider an external disruption of social, economic, or geopolitical origin, occurring unexpectedly and leading to a regime shift within the firm's operational environment. The objective of this research is to investigate how the firm should adjust its offshoring strategy in anticipation of and in response to such regime shifts. The problem is structured and addressed as a 2-stage optimal control problem with a stochastic switching time. The study aims to provide insights into proactive measures firms can employ to adapt their offshore operations effectively, mitigating risks and maintaining competitiveness in a dynamic global environment.

3 - Building resilience: a dynamic approach

Lijue Lu

In recent years we have witnessed various supply chain disruptions that severely affect the normal flow of goods and profitability. The purpose of this paper is to analyze a dynamic game that involves a supply chain dealing with a normal-disruption cycle, which is characterized by a random and unpredictable environment. The supplier can invest in building resilience to minimize the potential disruption's

impact. We derive the feedback equilibrium strategies and compare the policies and payoffs under different supply chain structures (centralized/decentralized). Finally, we propose a cost-sharing scheme to achieve coordination.

4 - A model-based measure for the resilience of resource use under the risk of disruption

Stefan Wrzaczek, Michael Kuhn

We study a simple economic-ecological framework of resource extraction that explicitly incorporates (i) a regimechanging shock and (ii) the possibility a resistance threshold/Skiba-point to lead to divergent behaviours towards either systemic recovery or system collapse following the shock. This structure allows us to model resilience (in the sense of regime-changing shocks either being avoided or systemic recovery being possible and optimal) and its behavioural implications in a meaningful way. Specifically, we propose a model-based measure of resilience that upon proper calibration of the model can be employed in numerical assessments of the implications for resilience of different extraction policies. We also study a simple example and show that anticipation of shocks is leading to precautionary behaviour that boosts systemic resilience.

Portfolio optimization

Stream: Stochastic, Robust and Distributionally Robust Optimization

Invited session

Chair: *Milos Kopa*

Chair: *Sebastiano Vitali*

1 - Simulation-optimization for dynamic bank asset allocation

Pedro Júdice

Bank asset allocation is a major determinant of banks' long-term performance and sustainability. Therefore, it is one of the most critical problems in bank management. Current bank asset allocation models fail simultaneously to use realistic scenarios and produce state-dependent asset allocations, so do not take advantage of the changes in business cycles. Using a multi-objective genetic algorithm, we develop a simulation-optimization method that determines dynamic asset allocation rules based on environment variables such as interest rates. Performance analysis on an independent testing set indicates that the algorithm outperforms other established methodologies, namely optimizing time-independent static allocations or choosing equal-weight policies. In addition to performance, we emphasize interpretability, developing an algorithm that allows results analysis and interpretation, and can thus be used in practice to support banks' senior management dynamic decisions.

2 - Bilevel models in portfolio selection problems

Monika Kal'atová, Milos Kopa

It is a common practice that an investor makes a decision based on not only in-sample efficiency, but also takes into account out-of-sample performance of the portfolios. To combine in-sample efficiency with out-of-sample optimality, one can employ a bilevel stochastic optimization problem. In our paper, the lower level of the problem consists of the mean-risk optimization model, where Conditional Value-at-Risk as a frequently used risk measure is applied. The upper level searches for in-sample efficient (lower level) portfolios with maximal out-of-sample performance (out-of-sample return).

The reformulation of the problem assuming a discrete probability distribution yields to a linear bilevel optimization problem. Additional

assumption can be made about variables in the upper level. In a moving window analysis, these variables can vary or remain the same for all windows. Therefore, two linear bilevel optimization problems with multiple followers are considered. One of them can be split in time, the other one not. The results for these two cases will be presented.

3 - Measures of Stochastic Non-Dominance

Jana Junova, Milos Kopa

We introduce measures of stochastic non-dominance to provide insights in situations when stochastic dominance between two random variables does not hold. They quantify how far a given random variable is from dominating a benchmark random variable by a specified order stochastic dominance. They are found by solving an optimization problem that searches for an optimal random variable, which is as close as possible to the given one but dominates the benchmark. The measure of stochastic non-dominance is then the Wasserstein distance between the optimal and the given random variable. Depending on the assumptions imposed on the optimal variable, we distinguish the general and the specific measures of stochastic non-dominance.

We derive closed-form expressions of the measures of stochastic non-dominance under various parametric assumptions. Moreover, we present relations to selected types of almost stochastic dominance. Finally, a formula is derived for the computation of the measures of stochastic non-dominance for discrete distributions with equiprobable atoms. It is applied to portfolio optimization problems in the empirical part.

4 - Investments in transmission lines and storage units considering second-order stochastic dominance constraints

Sebastiano Vitali, Miguel Carrión, Ruth Dominguez

Increasing intermittent renewable generation to meet the climate goals entails a deep transformation of current power systems. The transmission system must adapt to ensure a rapid and flexible response to the changes in the energy flows. Flexibility can be provided by reinforcing the interconnection among all the market agents and/or by installing facilities with fast response to the changes. In this work, we study the investment problem of a central planner that seeks to expand the transmission network and install storage units considering decarbonizing measures. We propose a two-stage stochastic problem with uncertainty on the demand growth and including representative days to characterize the hourly demand and renewable power variability. To obtain better expansion strategies according to a limit on the carbon emissions, second-order stochastic dominance constraints are imposed. Numerical analyses based on the power system of the Canary island (Spain) are provided. The results show that to install storage units is key to efficiently integrate renewable generation. The investments in the transmission system are mostly in lower-voltage lines. The formulation with stochastic dominance constraints results in higher second-stage investments, allowing a better adaptation to the demand growth evolution.

Stochastic Optimization with Decision-Dependent Uncertainty

Stream: Stochastic, Robust and Distributionally Robust Optimization

Invited session

Chair: *Giovanni Pantuso*

1 - Exact and Approximate Schemes for Robust Optimization Problems with Decision Dependent Information Discovery

Rosario Paradiso, Angelos Georghiou, Said Dabia, Denise Tönissen

Uncertain optimization problems with decision-dependent information discovery allow the decision maker to control the timing of information discovery, in contrast to the classic multistage setting where uncertain parameters are revealed sequentially based on a prescribed filtration. This problem class is useful in a wide range of applications, however, its assimilation is partly limited by the lack of efficient solution schemes. In this work, we study two-stage robust optimization problems with decision-dependent information discovery where uncertainty appears in the objective function. The paper's contributions are twofold: we develop an exact solution scheme based on a nested decomposition algorithm, and we improve upon the existing K-adaptability approximation by strengthening its formulation using techniques from the integer programming literature. We use the orienteering problem as our working example, a challenging problem from the logistics literature which naturally fits within this framework. The complex structure of the routing recourse problem forms a challenging test bed for the proposed solution schemes, in which we show that the exact solution method outperforms at times the K-adaptability approximation, however, the strengthened K-adaptability formulation can provide good quality solutions in larger instances while significantly outperforming existing approximation schemes even in the decision independent information discovery setting.

2 - Stochastic Queuing-Based Optimization Problems for Network Design

Miguel Lejeune

We study stochastic queueing-based optimization models to design networks in which the objective is to minimize the response time. The networks are modelled as collections of interdependent queueing systems in which the service times and the arrival of requests are random variables whose distribution parameters are determined endogenously. The optimization models take the form of nonconvex MINLP problems with fractional, exponential, and polynomial terms for which we propose a convex integer reformulation framework (MILP or convex MINLP).

3 - Solution of Two-Stage Stochastic Programs under Decision-Dependent Uncertainty

Giovanni Pantuso, Mike Hewitt

We present an exact solution algorithm for two-stage stochastic programs under decision-dependent uncertainty. In such problems, first-stage decisions determine the probability distribution of second-stage uncertain parameters. Particularly, we focus on a broad class of problems where the number of potential probability distributions is finite but exponentially large. The proposed method extends the well-known L-Shaped method and is applicable also to two-stage stochastic program with integer variables at both stages. We show that the new version converges finitely. In addition, we present results from a computational study based on facility location problems under endogenous uncertainty. The results provide promising evidence of efficiency and scalability.

4 - Solving Two-Stage Stochastic Programs with Endogenous Uncertainty via Random Variable Transformation

Maria Carolina Bazotte Corgozinho, Margarida Carvalho, Thibaut Vidal

Real-world decision-making problems involve decision-dependent uncertainty, where the probability distribution of the random vector depends on the model decisions. However, few studies focus on two-stage stochastic programs with this type of endogenous uncertainty, and those that do lack general methodologies. We thus propose a general method for solving a class of these programs based on random variable transformation, a technique widely employed in probability and statistics. The random variable transformation converts a stochastic program with endogenous uncertainty (original program) into an equivalent stochastic program with decision-independent uncertainty (transformed program), for which solution procedures are well-studied. Moreover, endogenous uncertainty usually leads to nonlinear nonconvex programs, which are theoretically intractable.

Nonetheless, we show that, for some classical endogenous distributions, the proposed method yields mixed-integer linear or convex programs with exogenous uncertainty. We validate this method by applying it to a network design and facility-protection problem, considering distinct decision-dependent distributions for the random variables. Whereas the original formulation of this problem is nonlinear nonconvex for most endogenous distributions, the proposed method transforms it into mixed-integer linear programs with exogenous uncertainty. We solve these obtained programs with the sample average approximation (SAA) method.

Game Theory, Solutions and Structures VII

Stream: Game Theory, Solutions and Structures

Invited session

Chair: *Thomas Lidbetter*

1 - Discontinuous Game and Nash Equilibrium

Inese Bula

We consider convex game with discontinuous payoff functions. A good overview of some key results in the literature on the existence of Nash equilibria in discontinuous games is given in [3].

We will look at the discontinuity in a certain form: we will look at w -continuous functions, which means that the discontinuity measure is not greater than the specified positive number w . Functions of this type can be approximated by continuous functions ([1,2]). If the approximation is also a concave or quasi-concave function, then a Nash equilibrium exists in the game. This equilibrium can be thought of as a quasi-Nash equilibrium with respect to the discontinuous payoff function of the original game. We would prefer that in the case where a Nash equilibrium exists in the original game, it is also found in a quasi-sense. If no equilibrium exists in the original game, then one would want the quasi-Nash equilibrium to provide the best possible solution. We will look at examples and conditions under which this is possible.

Discontinuous functions in Gale economic model. *Mathematical Modelling and Analysis*, V8(2), 93—102, 2003. [3] Reny, P. J. Nash Equilibrium in Discontinuous Games. *Annual Review of Economics*, V.12, 439—470, 2020.

2 - An enhanced gradient algorithm for computing generalized Nash equilibrium

Felipe Santos, Adriano Lisboa, Douglas Vieira, Rodney Saldanha

This paper introduces an enhanced algorithm for computing generalized Nash equilibria in multiple-player nonlinear games. The algorithm degenerates into a gradient algorithm for single-player games (i.e., optimization problems) or potential games (i.e., equivalent to minimizing the respective potential function), similar to the Rosen gradient algorithm. Analytical examples demonstrate that it has similar theoretical guarantees of finding a generalized Nash equilibrium when compared to the relaxation algorithm, while numerical examples show that it is faster. Furthermore, the proposed algorithm is as fast as, but more stable than, the Rosen gradient algorithm, especially when dealing with constraints and non-convex games. The proposed strategy is tested in benchmarking game theory problems and real-world applications.

3 - Strategic Behaviour in Priority Queues with Deadlines.

Jesse Nagel, Joris Slootweg

In many queueing systems customer satisfaction is determined more by the meeting of a deadline (missing a flight, service level agreements, etc.) than waiting time. We study the effect of such deadlines on strategic behaviour in priority queues. We model a queueing game where customers have a choice to pay a toll for priority access, allowing them to skip part of the queue. In this model, the meeting of the deadline is the most important factor in the utility functions of the customers. When looking at symmetric Nash equilibria in this model, we find Evolutionary Stable Strategy equilibria which do not exist in the model without deadlines. In addition, we model a heterogeneous situation where different groups of costumers have different deadlines and study how this influences social welfare and revenue.

4 - Optimal Pure Strategies for a Discrete Search Game

Thomas Lidbetter

Consider a two-person zero-sum search game between a Hider and a Searcher. The Hider chooses to hide in one of n discrete locations (or "boxes") and the Searcher chooses a search sequence specifying which order to look in these boxes until finding the Hider. A search at box i takes t_i time units and finds the Hider - if hidden there - independently with probability q_i , for $i=1,\dots,n$. The Searcher wants to minimize the expected total time needed to find the Hider, while the Hider wants to maximize it. It is shown in the literature that the Searcher has an optimal search strategy that mixes up to n distinct search sequences with appropriate probabilities. This work investigates the existence of optimal pure strategies for the Searcher - a single deterministic search sequence that achieves the optimal expected total search time regardless of where the Hider hides. We identify several cases in which the Searcher has an optimal pure strategy, and several cases in which such optimal pure strategy does not exist. An optimal pure search strategy has significant practical value because the Searcher does not need to randomize their actions and will avoid second guessing themselves if the chosen search sequence from an optimal mixed strategy does not turn out well. This is joint work with Thuy Bui and Kyle Lin.

Multi-objective optimization (MOO) is a technique widely used in engineering to balance different, often conflicting decision criteria that are difficult to compare directly. However, common methods for solving MOO problems, including the weighted sum, normal boundary intersection (NBI), and sandwich methods, often struggle in addressing the complexity of nonconvex and discrete decision variables in engineering designs.

In our research, we introduce a robust approach, referred to as SDNBI, that blends the sandwich algorithm with a modified version of the NBI method (mNBI). This new method is particularly effective in navigating the complex, non-linear parts of the decision space, and in quickly identifying areas where no further optimal solutions can be found. Our study explores the theoretical interplay between mNBI and the sandwich algorithm, focusing on three key aspects: the accuracy of its approximations, the decomposition of objective space based on Pareto front convexity, and its efficiency in circumventing redundant searches in disconnected Pareto segments. The effectiveness of this combined approach is benchmarked against existing MOO methods using standard literature problems and further validated in real-world scenarios such as solvent design for CO₂ capture and the design of working fluids in Organic Rankine Cycle processes.

3 - Bi-objective valve placement and control in an operational water distribution network using a hybrid evolutionary-deterministic method

Aly-Joy Ulusoy

We consider the valve placement and control problem, which consists in simultaneously determining the location and settings of new pressure control valves in water distribution networks for the optimization of performance (here, leakage reduction) at minimum cost. We present a hybrid method combining the complementary advantages of non-linear programming solvers and evolutionary algorithms to solve the resulting non-convex bi-objective mixed-integer non-linear program. The performance of the proposed algorithm is first evaluated on small case study networks from the literature. Our results show that the proposed hybrid method converges quickly to a good approximation of the Pareto front of the corresponding valve placement and control problems. Next, the hybrid method is applied to a large-scale operational network from the UK and obtained solutions are compared to the locations of existing pressure control valves (determined based on engineering judgement).

4 - Automated Grid Expansion and Reinforcement Planning Considering Multiple Objectives

Hendrik Maschke, Lars-Peter Lauen

The transition towards renewable energy sources presents increasing challenges in operating, maintaining, and planning electrical grids. With the growing complexity of planning tasks, various planning criteria impact the decisions on specific measures for grid reinforcement and expansion. To address such a growing number of criteria, it becomes necessary to develop suitable models and simulation tools. Therefore, an existing automated power grid expansion algorithm based on pandapower is enhanced to handle multiple objectives. So far, using stochastic local search algorithms like hill climbing or iterated local search, a solution has been found to minimize cost as the sole objective. In addition to cost, other objectives like reliability, security, sociology, or environment are often considered as well. A decision-support approach in grid planning is therefore proposed that considers these additional criteria. We propose a methodology that aims to optimize grid reinforcement and expansion by considering multiple objectives. The genetic NSGA-II algorithm is employed to find solutions that balance these considerations effectively. The approach aligns with sustainable development principles and fosters resilient and sustainable grid planning. Pareto front solutions, representing trade-offs between different objectives, offer a range of alternatives that can be considered in grid planning processes and therefore address the complex challenges of energy grid planning.

1 - Using Dual Relaxations in Multiobjective Mixed-Integer Convex Quadratic Programming

Gabriele Eichfelder, Marianna De Santis, Daniele Patria, Leo Warnow

We present a branch-and-bound method for multiobjective mixed-integer convex quadratic programs that computes a superset of efficient integer assignments and a coverage of the nondominated set. The method relies on outer approximations of the upper image set of continuous relaxations. These outer approximations are obtained addressing the dual formulations of specific subproblems where the values of certain integer variables are fixed. The devised pruning conditions and a tailored preprocessing phase allow a fast enumeration of the nodes. Despite we do not require any boundedness of the feasible set, we are able to prove that the method stops after having explored a finite number of nodes. Numerical experiments on a broad set of instances with two, three, and four objectives are presented.

1 - LEMON - an Open Source C++ Library for Solving Network Optimization Problems

Alpár Jüttner, Péter Madarasi

LEMON (Library for Efficient Modeling and Optimization in Networks) is a generic open source C++ library of graph and network algorithms and related data structures. It is a package of highly efficient and versatile tools with simple and convenient interface, targeting both computer scientists and the operations research community, both for academic and commercial purposes.

This talk will outline the basic design concepts, features and performance of LEMON, with a focus on the recent additions to the library. Then, two case studies are presented. The first one demonstrates how it may support basic research in Combinatorial Optimization, while the second one shows an example of industrial application.

2 - Efficient exact recomputation of linear modifications of the constraint matrix in Linear Programming

Guillaume Derval, Bardhyl Miftari, Damien Ernst, Quentin Louveaux

In this work we focus on linear parametric programming, where the constraint matrix is an affine function of an external parameter λ ; the goal is to assess the impact of λ on the objective value of the optimal solutions.

Computing the objective for multiple values of λ is usually cumbersome and involves solving the related linear program in full multiple times.

We show that by reformulating the problem in term an optimal basis for a given λ^* , we can use an eigendecomposition and Schur's decomposition to obtain an upper bound for the objective value for other values of λ . Moreover, the bound is actually tight when the basis stays optimal.

Given a solution for λ^* , the bound can be computed in quadratic time (in the number of constraints) for another λ . The range for the bound is exact can also be computed in quadratic time: this opens the way to an iterative algorithm for computing the full function, changing base each time the current one becomes invalid.

3 - A regularized interior point method for sparse optimal transport on graphs

Filippo Zanetti, Jacek Gondzio, Stefano Cipolla

In this talk, we address the solution of optimal transport problems using Interior Point Methods (IPM). We propose two approaches which exploit the expected sparsity of the optimal solution to enhance the efficiency of the numerical linear algebra required to solve the Newton system. The first approach deals with classical optimal transport over dense bipartite graphs, enforcing sparsity of the intermediate approximations by means of a column-generation-like approach. The numerical experiments show that this method can achieve scalable results for very large problems. The second approach deals with optimal transport over sparse graphs, using a proximal stabilized interior point method. The induced primal-dual regularization allows to use sparsified versions of the normal equations to inexpensively generate IPM search directions. The proposed method, despite a potential high level of inexactness in the Newton direction, retains the polynomial complexity of standard IPMs, for suitable choices of the sparsification parameters. Numerical results show that this approach is efficient and robust for

large scale problems, and can outperform classical graph algorithms like network simplex and cost scaling.

1 - Competition and Cost in a Dual Sourcing Supply Chain

Jizhou Lu

In a supply chain with a manufacturer ordering from two competing suppliers, this study examines how information quality affects information sharing's value and supplier competition. Market demand follows a time-series model. All members use periodic inventory reviews, order-up-to policy, and MMSE forecast method. We analyze various combinations of three information-sharing situations and four information-quality levels. Results show: 1. Supplier demand rises with competitive power, but increased orders mean higher inventory costs and potential savings through sharing. Suppliers should balance these to find optimal competitiveness and gain advantage. 2. Different information errors impact supplier competition. For instance, transmission errors might give one supplier an edge when the manufacturer shares data with both, while source errors do not. 3. Differentiation, including information status and quality, leads to competitive advantage. Suppliers should negotiate for exclusive sharing when no errors or only source errors exist. For transmission errors, enhancing information quality management is advised.

2 - Multi-product stochastic inventory problem with business overdraft

Zhen Chen

We consider a multi-product stochastic inventory problem in which the retailer faces cash constraints but it can leverage business overdraft to deal with unexpected cash shortage. We propose a stochastic programming formulation for this problem and apply stochastic dual dynamic programming (SDDP) to solve it. Some of the improvements of SDDP are considered and developed to make the algorithm more computationally efficient. Finally, numerical experiments are conducted to evaluate the performance of SDDP and obtain managerial insights.

1 - A Natural Hermite dissimilarity index randomization for the design of pre-clinical studies, based on a genetic algorithm.

Sofia Weigle

Algorithms for randomization of animal studies such as Irini (Weigle et al 2023) are used to allocate the subjects of a study at random into experimental groups. This paper presents a new method that offers an alternative to Irini random allocation a new criterion based on the Natural Hermite index. The idea is that instead of comparing variables across samples individually, the new method compares the multivariate density estimators of the populations. A new method called differential Natural Hermite index was introduced in order to measure the dissimilarity among the multivariate density estimators of the various populations, and it was minimized by applying a genetic algorithm. The genetic algorithm implements a process similar to the Theory of Evolution, for minimizing the differential Natural Hermite dissimilarity for partitions of a dataset into balanced subgroups. Simulations were performed for comparing the new dissimilarity to IRINI and to random allocation via exhaustive search. The simulations demonstrated the performance superiority of minimizing a fully multivariate dissimilarity such as the Natural Hermite one instead of the combination of univariate dissimilarities implemented by the Irini criterion. The Natural Hermite index that was able to find better partitions than the other two algorithms at a very comparable computational expense.

2 - Principal Phrase Mining: An Automated Method for Extracting Meaningful Phrases from Text

Ellie Small

Technological advances have resulted in an explosion of information in all aspects of society. Much of this information is unstructured in the form of text. Being unstructured means that machine learning and artificial learning techniques cannot be applied. The text mining field allows the extraction of frequent words from collections of texts in order to obtain summary information in a more structured format. Machine learning techniques and artificial intelligence may then be applied to this structured data. However, as useful as it is to obtain a collection of commonly occurring words from texts, more specific information may be obtained from texts in the form of commonly occurring phrases. Despite this need, extracting frequent phrases is not commonly done due to inherent complications, the most significant being double-counting. Double-counting occurs when words or phrases are counted when they appear inside longer phrases that themselves are also counted, resulting in a large selection of mostly meaningless phrases that are frequent only because they occur inside frequent super phrases. Several papers have been written on phrase mining that describe solutions to this issue; however, they either require a list of so-called quality phrases to be available to the extracting process, or they require human interaction to identify those quality phrases during the process. In addition, those methods are often very time-consuming.

3 - Forecasting high dimensional Tensor with relatively few observations.

Nuria Diaz-Tena

When studying excess Covid deaths in the 50 US states, the responses is a tensor time series of 50 states by 15 major causes of deaths and the overall. This data is observed monthly since 2015 before covid until 2023 and the objective is to estimate the excess deaths during covid years. We propose a model that combines a non-linear trend model that explains the over-all structure of the data, followed by a seasonality model, and a tensor autoregressive model for the residuals. The seasonality model consists in a combination of sinusoidal trends at different frequencies. The results give clear patterns of excess deaths by state and disease during covid time that can be communicated and interpreted with data visualization.

1 - A Subgradient Methods for general invex non-smooth vector optimization problems.

Arunima Kumari

Vector Optimization problems have a wide range of applications in various fields, like economics, decision theory, game theory, information theory and optimal control theory. In this paper, unlike the general scalarization techniques, a sub gradient method without a scalarization approach is proposed for minimizing a non-differentiable invex function which works directly with vector valued functions. The proposed method includes regularization and the interior points variants of Newton's Method. The proposed algorithm generates a sequence of efficient points in the interior of epigraph of objective function which satisfy Karush-Kuhn-Tucker conditions.

2 - Subgradient Methods for Nonsmooth Fractional Optimization Problems over the Fixed-Point Constraints

Mootta Prangprakhon, Nimit Nimana

We consider a class of nonsmooth fractional optimization problems over the fixed-point constraints, where the numerator is a convex function and the denominator is a concave function. To solve this problem, we propose iterative algorithms whose idea is to perform subgradient steps with respect to the convex numerator and the concave denominator separately. Under certain assumptions, we obtain the convergence properties of the proposed methods. Furthermore, to tackle large-scale optimization problems, we propose an incremental subgradient algorithm to deal with the case where the objective function is a sum-of-ratios fractional optimization problem.

3 - Calculating of weak subgradients and radial epiderivatives and applications in nonconvex and nonsmooth optimization

Refail Kasimbeyli

This work presents some calculus rules and new properties of the weak subgradients and the radial epiderivatives. The weak subgradient and the radial epiderivative concepts are based on the conical supporting methodology and therefore are able to characterize global behavior of a function under consideration and hence are used as a conical underestimation for nonconvex functions satisfying the Lipschitz condition from below. These generalized derivatives are used to establish global optimality conditions and to develop solution methods in nonconvex and nonsmooth optimization. Although the radial epiderivative concept can behave as the classical directional derivative in particular cases, it can be used to characterize and generate optimal solutions for many optimization problems that are impossible to handle with classical ones. In this work we present illustrative examples and demonstrate how the weak subgradients and the radial epiderivatives can be calculated for special classes of functions. The work presents applications for some classes of nonconvex and nonsmooth optimization problems.

4 - A bundle-type method based on descent-ascent directions for solving nonsmooth DC programs

Giovanni Giallombardo, Manlio Gaudioso, Giovanna Miglionico

We present a bundle method for the unconstrained minimization of nonsmooth difference-of-convex functions, which is based on the calculation of descent-ascent directions. In fact, we define a descent-ascent direction as a direction which is expected to simultaneously provide a descent for the minuend component function, and an increase for the subtrahend component function. The algorithm only requires evaluations of the minuend component function at each iterate-point, and it can be considered as a parsimonious bundle method, as accumulation of information takes place only in case the descent-ascent direction does not provide a sufficient decrease. Hence, bundle-resets take place every time a sufficient decrease in the objective function is achieved. No line search is performed, while proximity control is pursued independent of whether the decrease in the objective function is achieved. Computational performance of the algorithm, which is proved to terminate at a point satisfying a weak criticality condition, are reported relative to a set of benchmark DC instances, ranging from small to large size.

1 - The Geometry of Sparsity-Inducing Balls

Michel De Lara, Jean-Philippe Chancelier, Lionel Pournin, Antoine Deza

Sparse optimization seeks an optimal solution among vectors with at most k nonzero coordinates. This constraint is hard to handle, and a strategy to overcome that difficulty amounts to adding a norm penalty term to the objective function. The most widely used penalty is based on the l_1 -norm which is recognized as the archetype of sparsity-inducing norms. In this talk, we present generalized k -support norms, generated from a given source norm, and show how they contribute to induce sparsity via support identification. In case the source norms are the l_1 - and the l_2 -norms, we analyze the faces and normal cones of the unit balls for the associated k -support norms and their dual top- k norms.

2 - Partially non-convex minimax theorem and applications to remoteness of sets and functions

Mohammed Ibrahim Abdelkayoum Ghitri, Abderrahim Hantoute

We propose two new variants of the well-known Fan's minimax theorem, weakening the assumptions of convexity and lower semi-continuity used in the convex-concave standard version. Namely, the convexity and lower semi-continuity are only required on a smaller set which does not have to be convex or compact. In this case, the bi-function may take extended values on the given pair of convex sets. A second variant is then given when the bi-function is finite on these sets, removing the lower semi-continuity condition. These results are next used to study the remoteness of sets and functions in Hilbert spaces. Key words: Minimax theorem, convexity, remotal sets and functions.

3 - Advances on the sharp Hoffman constant of the argmin mapping

Jesús Camacho, María Josefa Cánovas, Helmut Gfrerer, Juan Parra

The aim of this talk is to introduce an exact point-based formula (involving only the problem data) for the Hoffman constant of the argmin mapping in linear optimization, which can be considered as the sharp Lipschitz constant restricted to its domain. The work is developed in the parametric context of right-hand side perturbations of constraint systems. To achieve our goal, we develop a new concept of its own interest, called well-connected piecewise convex mappings. Indeed, optimal set mappings fall into this new classification of mappings, for which we provide a recursive construction to derive a crucial equality between the Hoffman constant and the supremum of the calm moduli.

4 - Non-active constraints in convex infinite optimization

Abderrahim Hantoute

We provide optimality conditions for general convex infinite optimization problems in absence of compactness assumptions. Hence, no pre-requisites are considered on the constraints index set and no continuity-like behavior is assumed on the dependence of these constraints with respect to the parameters. The resulting KKT and Fritz-John conditions involve only the objective and the constraint functions, enlightening the different roles played by the (almost) active and non-active constraints. Namely, the Lagrange multipliers associated with non-active constraints can be made very small. The main ingredient is new representations of both the subdifferential of the supremum function and the normal cone of its effective domain.

1 - Spatio-temporal pricing of battery-swapping tasks on mobility-sharing platforms using proximal policy optimization

Minjeong Kim, Ilkyeong Moon

Battery-powered mobility-sharing companies face operational challenges in managing low-battery mobilities due to the dockless service, allowing pickups and drop-offs anywhere. To tackle this, such companies engage independent contractors to recharge these mobilities, offering them per-task compensation. Given the contractors' liberty to dictate their work schedules and volumes, it is essential to devise a pricing strategy to motivate their participation. The core tradeoff involves balancing the wages paid to workers against the penalty costs from unsatisfied customers due to incomplete charging tasks. To this end, this study proposes a spatio-temporal pricing strategy that assigns tasks with differentiated regional prices by time interval, aiming to attract workers to areas with a scarcity of available workers. We use a reinforcement learning approach with proximal policy optimization to handle the high dimensionality of the problem. A simulation environment mimics dynamic worker participation and task reservation in response to price updates made by the RL agent. Computational experiments demonstrate the effectiveness of reducing overall platform costs under varying task and worker distributions. Moreover, the findings indicate that the RL-driven pricing policy mitigates the spatial and temporal discrepancies between task demand and worker availability. Our study is applicable to other spatial crowdsourcing platforms which necessitate resolving spatio-temporal imbalances.

2 - Multi-Agent Airline Integrated Planning and Scheduling Under Demand Uncertainty

Mahdi Noorafza, Bruno Filipe Santos, Alexei Sharpanskykh

Integrated planning and scheduling are crucial aspects of airline management, especially when dealing with uncertain passenger demand. A common strategy to tackle this challenging approach is to develop partially integrated optimization models. While existing research deploys these partial models in stages, this study introduces a framework based on a multi-agent system model that combines fleet planning, network planning, and flight scheduling into a single model. Our framework provides a comprehensive solution to the challenges arising from the complex interactions between fleet acquisition decisions, network design, and flight timetables in an airline. The planning and scheduling are carried out through computational agents representing departments and individual decision-makers within an airline. A demand scenario tree is utilized to model demand uncertainties in the future. Nodes in the scenario tree contain similar computational agents and receive demand input associated with that node. The final plan is generated using an innovative collaborative multi-agent planning algorithm that allows information exchange between agents within each node and the nodes themselves. The framework can accommodate detailed operational constraints of the airline, enabling the tailored identification and evaluation of potential operational improvements. Finally, we demonstrate the application and potential improvements of the framework in several cases.

3 - Exploring the trade-off between efficiency and equity of urban public charging investment: an agent-based simulation study

Tanxiaosi Luo, Yanqiu Song, Junlin Chen

The allocation of urban public charging resources plays a crucial role in facilitating EV diffusion. As a public resource, electric vehicle charging infrastructure (EVCI) also faces the conflict between equity and efficiency for its distribution, necessitating consideration of how to balance these two allocation principles. However, current research lacks in-depth exploration of the trade-off between equity and efficiency in the EVCI layout. Therefore, this paper uses an agent-based model (ABM) to depict the complex dynamic relationship between EVCI investment and EV diffusion, aiming to capture the evolution of EV uptake under different EVCI distribution principles. Empirical data from Beijing is further applied to calibrate and validate the model before conducting simulation experiments to analyze which principles should be prioritized with limited resources to fully realize the role of EVCI in promoting transportation electrification. Findings suggest the efficiency-oriented allocation strategy is clearly superior to the equity-oriented allocation strategy at the innovation and growth stage of EVs, and both are better than the baseline scenario. It is indicated that efficiency should be prioritized for EVCI allocation at the beginning stage of EV diffusion, which can eventually achieve a trade-off between efficiency and equity when the EV market matures.

4 - A Stakeholder-Based View of Business Cases for Integrated Urban Transport

Lena Hörsting, Catherine Cleophas

Integrating urban parcel transport into a public passenger transport system is a promising concept to reduce traffic congestion and to use resources more efficiently. However, the last decade saw several promising pilot projects failing due to the lack of long-term support and profitability. Existing reviews show that financial viability is an important aspect for the long-term success of such projects. Integrated transport relies on a range of stakeholders, which differ in their incentives and want to profit from the system. For example, partially financing the public transit system with the revenue gained from parcel transportation may contribute to the success of a shared transport system from the point of view of public transit providers. In this talk, we first describe the views of relevant stakeholders based on a review of the literature and case studies. Further, we propose performance indicators to evaluate a shared passenger and freight system from the perspective of the individual stakeholders. Secondly, we conceptualize an agent-based simulation model to evaluate business cases for a shared passenger and freight network.

1 - Applying MCDA to Determine Eligibility for Pardon

Irit Talmor

During certain national festivities, nations occasionally grant mass prisoner pardons based on specific standards. In this study, we introduce a novel technique to determine which prisoners qualify for early release using a multi-criteria decision analysis (MCDA). The criteria used were gender, age, crime severity, proportion of sentence completed, and behavior while in jail. Criteria weights were calculated using the analytical hierarchy process (AHP), based on data provided by the authorities. The model produced transparent and impartial results, offering decision-makers a convenient and efficient tool.

2 - AHP and Nonlinear Optimization to Improve Market-Value Appraisal of Real Estate Assets

Sergio Copiello, Carlo Grillenzoni, Pietro Bonifaci

In real estate appraisal, the market value of a property is often identified based on the principle of price equilibrium; thus, the prices of similar, recently traded real estate assets are the basis for the assessment. Under this framework, a technique widely used by practitioners and appraisers goes under the name of sales comparison adjustment grid. The property to be assessed (the so-called subject) is compared to ten or so transactions (the so-called comparables). Adjustments are made to the comparables' prices to reflect their differences with respect to the subject. To that end, the properties' main attributes - namely, the features the market players on the demand and supply side value the most - must be listed and weighted. The weighting of the attributes - usually based on the appraisers' local real estate market knowledge - is among the most prominent weaknesses of the appraisal technique. We propose to improve it by deriving the weights from the data itself using a model combining the methodological setting of the Analytic Hierarchy Process (AHP) and nonlinear optimization. On the one hand, a ranking of the comparables is derived by the pairwise comparison of their prices. On the other hand, another ranking is derived by the pairwise comparison of their attributes. The weights of the attributes are then iteratively searched as those that minimize the distance between the two rankings.

3 - Comparing two MCDM Approaches to Evaluating Corporate Governance

Kao-Yi Shen

This study aims to analyze corporate governance using Rough Set Theory (RST), highlighting its significance in both academic discourse and industrial practices. Corporate governance plays a pivotal role in ensuring trust and protection for investors, effective risk management, enhanced corporate performance, fulfillment of social responsibility, and adherence to legal and regulatory compliance. This study compares a bipolar model based on RST with a traditional multi-attribute decision model. The objective is to evaluate the effectiveness and distinguishing characteristics of the RST-based bipolar model compared to conventional multi-attribute decision models. The RST-based model introduces a unique perspective that deviates from the traditional approaches of multi-attribute decision-making. Through this comparative analysis, the study aims to provide valuable insights into the application of RST in decision-making frameworks, contributing to a deeper understanding of its practical implications in decision science. Through rigorous analysis, the research identified distinct characteristics and performance metrics of the RST-based bipolar model. It assessed its efficacy in decision-making contexts—key findings shedding light on the model's strengths and potential areas for improvement. The comparative analysis enhances our understanding of the practical implications of employing RST in decision science, providing valuable implications for academia and industry.

4 - Computation of the Maximum Eigenvalue of the Pairwise Comparison Matrix in the Analytic Hierarchy Process

Shunsuke Shiraishi, Tsuneshi Obata

This talk deals with a pairwise comparison matrix of the analytic hierarchy process. We show the convergence results of Newton's and secant methods for finding the maximum eigenvalue of the pairwise comparison matrix. In recent years, we have shown similar results for lower-order (3-rd and 4-th order) pairwise comparison matrices. The proof was based on our representation formula for characteristic polynomials. In this talk, we will report that we can extend the result to the general order of the pairwise comparison matrix. The proof relies intensely on the Gauss-Lucas' theorem on the zeros of polynomials and their derivatives. We also give computational simulation results for 4-th order pairwise comparison matrices. We randomly provide pairwise comparison matrices of Saaty's discrete scale and count the iteration numbers of Newton's, secant, and bisection methods, respectively. The simulation gives insight into the superiority of Newton's method compared to the secant and bisection methods.

Integer Programming for Decision Support

Stream: Decision Support Systems

Invited session

Chair: Janusz Miroforidis

1 - A Multiple Criteria Mixed Integer for the Parallel Machine Scheduling Problem Programming Model: Common Sourcing

Tugce Yucel

Companies have to use all their resources in an optimum way in order to be successful in a competitive environment. One of the important approaches in recent years is the effective use of the workforce and the effective use of human resources in order to achieve efficiency. Different in industry for production environments, widely parallelized to minimize production time in different production environments machine scheduling problems are used. In this study, it was applied in a defense industry company in Turkey. A multi-criteria mixed integer programming model has been developed for more efficient planning on two identical NC machines. The aim of the model is to minimize the total delay time and total completion time of the jobs. The aim is to ensure that many parts of different projects are correct on the cutting benches minimizing total delay and total completion time according to prioritization and under certain constraints. In addition, an iterative heuristic approach based on a mathematical model has been developed for the problem size for which the mathematical model is not sufficient. The methodology used is to increase the efficiency of the company by improving the total time to completion, maximum latency, total latency and number of delayed jobs.

2 - Decision Support Model for Incomplete Risk-Seeking Preferences

Peng Xu, Tri Tran

Risk-seeking behavior has been extensively documented across various research fields such as decision sciences, economics and finance, psychology. In this research, we propose a decision support model based on reverse second-order stochastic dominance (RSD) to accommodate incomplete risk-seeking preferences. Specifically, we establish dominance conditions according to the RSD criterion in discrete state-space. We then develop a stochastic optimization model that enables to identify an optimal decision alternative whose dominance over a pre-specified benchmark is robust for all risk-seeking decision makers. Furthermore, we demonstrate that RSD-based optimization model can be formulated as a mixed-integer linear programming problem to generate decision recommendations. The developed decision support model is well-suited to support data-driven decision analytics problems, including production and operations management, logistics and supply chain management, and healthcare management, particularly in the presence of incomplete preference information.

3 - A hybrid decision-making support method for large-scale multi-objective mixed integer programming problems

Janusz Miroforidis

Many practical multi-criteria decision-making problems are formulated using Multi-Objective Mixed Integer Programming (MOMIP). Among many methods of multi-criteria decision-making, interactive ones are considered the most rational. In interactive methods, Chebyshev scalarization and MIP solvers can be used to derive efficient outcomes. However, for a large-scale instance of the MOMIP problem, even commercial solvers may not provide the optimal solution of its scalarization within a time limit, and its existence is justified in practice. In such a case, the applicability of interactive methods becomes questionable because this interactivity is lost when the time limit is on the order of many minutes. In this work, for large-scale instances of the MOMIP problem, a hybrid decision-making support method is

proposed. It combines features of interactive and a posteriori methods. Before the decision-making process begins, a finite two-sided Pareto front approximation is derived with the help of a MIP solver. It is used to calculate the so-called interval representations of Pareto optimal outcomes designated, directly or not, by weights of Chebyshev scalarization. Decision-makers can use them to reveal their preferences without additional optimization calculations. The use of the proposed method is demonstrated with selected large-scale instances of the MOMIP problem with two and three objective functions. Its limitations and possible enhancements are also discussed.

4 - Enhancing Decision-Making in Agricultural Policies: A Four-Step SWOT Protocol

Janja Rudolf, Andrej Udovc

The protocol underwent rigorous testing in the agricultural sector, focusing on collective agri-environmental and climate schemes. While these initiatives hold potential (Pe'er et al., 2020), they often lack numeric data and standardized indicators, hindering comparisons (Rudolf in Udovc, 2022). Consequently, decision-makers face challenges in assessing their impact on the environment and public goods. The protocol consists of four steps. In first step, SWOT results from various case studies are gathered, focusing on factors that impact the same goal. These results are then grouped into common themes and subthemes using the Stirling method (2001), creating a hierarchical decision tree of attributes. In second step, analytical hierarchical process is used to calculate the weights of SWOT factors and attributes, incorporating input from multiple professionals. In third step, a customized form is created for decision-makers to list SWOT factors for their specific case, following the decision tree of attributes. This form is linked to a tailored transformative formula, converting qualitative SWOT analysis into quantitative values. Building on the SWOT scorecard technique (Rudolf and Udovc, 2022), this formula adjusts using the individual weights assigned to SWOT factors in step two. The fourth step arranges numeric codes into groups, representing levels on a Likert scale. These levels are recognized within a model, aiding in the evaluation of case studies.

1 - Enhancing Local Sustainable Development: A Digital Spatial Decision Support System to Recovery Marginal Areas in Italy

Maurizia Pignatelli

Urban areas are undergoing a digital transition of spatial planning systems. This transition implements advanced infrastructure technologies to define future scenarios efficiently. Spatial support system tools supporting sustainable development and help local governance processes to make better decisions. However, spatial planning systems at the local level often fail to adapt to small-scale and local social innovations, particularly in marginalized areas, highlighting the need for improved integration of digital technologies. The study aims to create an interactive web-GIS dashboard, serving as a digital Multicriteria Spatial Decision Support System (MC-SDSS), to assist local authorities in fostering a responsive environment for future local policy actions aimed at recovering sustainable local development. The methodological framework of this study is structured in two parts: (I) Define an evaluation framework based on the set of Key Performance Indicators (KPIs) and perform the spatial impact assessment in four pilot case studies (II) Develop an interactive web dashboard consisting in KPIs through the use of GIS for setting targets and strategies through the implementation of Multicriteria Analysis (MCA) and a Social Design System Thinking (SDST) approach. The results demonstrate the operability of the web dashboard and the key findings of its implementation in the case studies, providing a set of suitable strategies and actions to recover sustainable marginal areas.

2 - Reviewing Micromobility Modes of Paris City by novel MCDM Approach: Extracted Framework Element Effect (EFEE)

Esra Çakir, Çağrı Tolga

The assessment of micromobility in Paris is essential for aligning urban transportation practices with the climate targets set by the European Union, fostering sustainable mobility solutions to mitigate greenhouse gas emissions and promote environmental stewardship. This study presents an innovative approach to evaluating micromobility modes in the urban context of Paris through the application of the Extracted Framework Element Effect (EFEE) methodology within a Multi-Criteria Decision Making (MCDM) framework. The EFEE approach analyzes the impact on overall evaluation when specific criteria are systematically extracted, revealing the relative importance of each criterion in Euclidian environment. Various micromobility options, such as e-scooters, bike-sharing, and emerging alternatives, undergo scrutiny based on criteria relating to their environmental impact, accessibility, safety, and efficiency. Moreover, the research delves into assessing the alignment of these evaluated micromobility modes with the European Union's 2050 climate targets, with a particular emphasis on reducing greenhouse gas emissions and fostering sustainable transportation practices. The findings provide insights into the efficacy of micromobility modes in mitigating climate change and advancing sustainable urban mobility. Ultimately, the study aims to inform policymakers, urban planners, and stakeholders in Paris about the role of micromobility in achieving the EU's long-term climate objectives.

3 - Decision-Making Models of House Purchase Among Different Age Groups

Chia-Wen Liao, Min-Jun Wu

The rapid rise in real estate prices around the world has attracted widespread attention. The reasons for the rise in real estate prices

include insufficient land supply, population growth, economic development, investment demand, and other factors. Several surveys show that average house prices are rising faster than average wages, causing many families to face difficulties in house purchases. In Taiwan, people generally feel the pressure of house purchases. High housing prices relative to average wages require residents to face longer repayment periods and higher loan interest rates during the process, exacerbating the difficulty of house purchase. In addition, unequal development among regions has also led to great different considerations for house environment in different regions. House purchase decisions of different age groups are affected by many variables. The number of years and amount of the loan directly affect the repayment pressure and quality of life, while the average transaction price per square meter of houses is an important factor affecting the choice of living area. This paper takes Taiwan as an example. We focus on different districts in Taipei City of Taiwan. The views and difficulties faced by people on house purchase are discussed. Based on survey data, including housing prices and average salaries, the different decision-making models between old, middle-aged, and young generations of dual-income couples in house purchase are presented.

4 - Evaluating social impacts of adaptive reuse of public buildings: a Multi-Criteria Decision Analysis approach

Marta Bottero, Alessandra Oppio, Danny Casprini, Giulio Cavana, Federico Dell'Anna

Adaptive reuse in architecture and urban planning refers to the repurposing of existing buildings for new uses. Several and diverse sustainability benefits are associated with this practice, including prevention of soil consumption and natural resources depletion, limiting construction and demolition waste production, and saving costs. With specific reference to social outcomes, adaptive reuse of buildings can generate positive effects such as revitalizing local communities, valorizing cultural heritage, providing new services for the inhabitants, creating new jobs, to name a few. These effects are even more relevant in the case of reuse projects concerning public buildings, where there is a strong need to guarantee the legitimacy of the decisions made according to a social purpose. The present contribution explores the evaluation of social impacts in adaptive reuse of public buildings, and it proposes a multidimensional framework based on Multi-Attribute Value Theory (Keeney and Raiffa, 1976) for the construction of a synthetic impact score to rank alternative projects.

1 - Electric Vehicle and Charging Infrastructure Growth in Indian States: Assessment using a modified PCA- DEA Application

E Sandhiya, M. S. Gajanand

In recent years, the rapid proliferation of economic activities in India has been accompanied by a surge in the demand for electric vehicles (EVs). Following the Paris Agreement, India has set ambitious targets for reducing carbon emissions, including the "30@30" goal. However, with varying economic and demographic characteristics in India, EV adoption presents unique challenges and hinges on the development of a robust, equitable, and strategically planned charging infrastructure. This is because, while the global average indicates that we need to have at least one charger per 10 EVs, the current EV to public charging infrastructure in India is 181:1. In this study, we analyse the growth of EV ecosystem across Indian states. Based on the literature, we first identify the various factors that affect the EV ecosystem. Using Principal Component Analysis (PCA), we construct a comprehensive measure

of these factors by grouping them into similar themes and then evaluate the performance of the Indian states using a modified Data Envelopment Analysis (DEA) approach. This comprehensive approach will not only provide valuable insights for policymakers but also pave the way for targeted interventions aimed at accelerating the transition towards a sustainable electric mobility future. Additionally, we suggest targeted interventions for states with lower scores, focusing on policy enhancement and infrastructure investments to accelerate their progress in the electric vehicle ecosystem.

2 - Measuring the efficiency of humanitarian supply chains in face of disasters using a network data envelopment analysis

Majid Azadi

Over the past few there have been so many disasters around the globe mostly due to climate change and pandemics. To deal with natural and man-made disasters efficient humanitarian supply chains have attracted significant attention. To benefit from efficient humanitarian supply chains there has been focus on efficiency measurement using novel systems, frameworks and models. In spite of the significance of measuring efficiency in humanitarian supply chains, there are still some key barriers with the current efficiency measurement using novel systems, frameworks and models. The goal of the current study is developing a new network data envelopment analysis (NDEA) model that contains a number of distinctive advantages. In this paper the divisional and overall efficiency of humanitarian supply chains are measured using our novel model correctly. Moreover, our developed model can address all types of data in the process of measuring the efficiency of humanitarian supply chains. We presented a case for our developed model along with some managerial insights.

3 - Coastline Sensitivity Analysis for Oil Spill Mitigation: A Not-oriented Slack-based Data Envelopment Analysis Approach

Danijela Tuljak-Suban, Valter Suban

Oil spills are a constant threat to marine ecosystems and coastal communities. One of the critical aspects of oil spill response is the placement of oil booms. The decision of where to place oil booms is complex as it depends on several factors, including the location of the spill, the nature of the coastline and the potential for environmental and economic damage, especially to the local community. In this paper, a not-oriented slack-based data envelopment analysis (NO-SBM-DEA) approach is proposed to evaluate coastal sensitivity to oil spills. The NO-SBM-DEA approach considers the key aspects of coastal sensitivity: geomorphology, socio-economic and environmental aspects. The specifics of all variables are taken into account when calculating an overall performance score so that there is no need to switch between input and output orientation. The proposed approach provides a comprehensive and objective assessment of coastal sensitivity that can guide the placement of oil booms in the event of an oil spill. All data originate from studies carried out within the North Adriatic Incident Response System (NAMIRS) project. The proposed method was also applied to a case study in the northern Adriatic Sea to demonstrate its potential as a valuable tool for global oil spill mitigation efforts worldwide. The method provides an objective and transparent tool for assessing the sensitivity of coastal areas and can help ensure that oil booms are placed in the most effective locations.

4 - Shadow Pricing of Nitrogen Surplus in Lithuanian Family Farms

Tomas Balezentis, Vida Dabkiene

We use the slacks-based data envelopment analysis model to obtain the shadow prices of nitrogen surplus in a sample of Lithuanian family farms over 2014 and 2019. The variable returns to scale weak disposability technology is assumed. The results indicate that the shadow price obtained for Lithuanian cereal farms is relatively low compared to the earlier literature. This implies that the environmental performance of Lithuanian cereal farms needs to be improved (especially, the fertilizing regime).

1 - Mechanism design for job reassignments in collaborative manufacturing

Margaretha Gansterer, Dominik Zehetner

The remarkable success of sharing economy platforms in the B2C sector has led to increased attention from both practitioners and researchers seeking to apply these models to the B2B sector. Studies have already demonstrated that combined with cloud manufacturing and additive manufacturing, these concepts can considerably reduce costs while the responsiveness supply chains is increased. However, there is a need to design resource allocation mechanisms such that desirable properties are to be achieved. Promising approaches for such an environment are decentralized combinatorial auction frameworks that can be used to exchange jobs to decrease production costs of operations efficiently and effectively. In our approach, machines autonomously select jobs from an existing production plan to forward them to other suppliers that can produce these parts for lower costs. An auctioneer creates promising part bundles and manufacturing machines autonomously place bids on the packages via a combinatorial second price reverse auction. Costs of the reallocated bundles are shared throughout a Shapley value-based approach without the need to disclose critical information. We provide analytical and numerical insights on this approach and show if and how desirable properties such as budget balance, incentive compatibility, and individual rationality can be achieved.

2 - Supply contracts with investment cost sharing under arbitrary bargaining powers

Pyung-Hoi Koo, Young Jin Kim, Chang Seong Ko

In this study, we propose a novel coordinated supply contract scheme integrating bargaining power (BP) considerations with capacity planning. Our scheme empowers manufacturers to design supply contracts conducive to channel coordination under arbitrary BP scenarios. It comprises two supply contracts: capacity cost sharing (CCS) and surplus capacity compensation (SCC) contracts. In the CCS contract, the manufacturer shares a portion of the supplier's capacity investment cost in a revenue-sharing framework. Conversely, the SCC contract entails the supplier bearing the cost of unused capacity. These contracts incentivize the supplier to invest in production capacity in alignment with the overall supply chain capacity, regardless of the BP scenarios. We demonstrate that our contract scheme can satisfy any BP structure. Specifically, the SCC contract facilitates channel coordination under higher supplier BP, while the CCS contract leads to coordination under lower supplier BP. We also analyze the interrelation between contract parameters for channel coordination and establish the relationship between bargaining power and optimal supply contracts. Our findings reveal that revenue sharing and capacity cost sharing fractions are positively proportional to each other in the coordinated CCS contract, and the compensation rate for the surplus capacity increases as capacity cost sharing rate increases to achieve a coordinated SCC contract.

3 - Cost Allocation Mechanisms in a Capacitated Economic Lot-Sizing Game

Basak Altan

In this paper, we consider a capacitated economic lot-sizing problem where companies determine the optimal joint order plan in order to meet their demands in the most cost effective manner for a given planning horizon. After determining the minimum cost solution of the collaboration, the resulting joint-cost is to be allocated among the collaborators appropriately in order to sustain the collaboration. We first prove that the core of the corresponding cooperative game may be

empty. Next, we establish the necessary and sufficient conditions for this game to have a non-empty core and show that when these conditions are satisfied, we can obtain a core allocation by solving a dual problem of a tight LP-relaxation. We also establish the equivalency of the dual optimal solution set and the core allocations when they exist and satisfy equal treatment of equals. Finally, we propose five different cost allocation mechanisms: (i) marginal allocation, (ii) dual linear programming based mechanism, (iii) the Shapley Value, (iv) the Nucleolus, and finally (v) pattern-based mechanism. Based on an extensive computational study, we observe that the pattern-based allocation mechanism significantly outperforms the other mechanisms with respect to the fairness of the cost allocations.

4 - Exact and Heuristic Methods for Multi-agent Scheduling of Shared Manufacturing Systems

Ege Duran, Cemalettin Ozturk

The progress of digitization and the emergence of resource-sharing business models have brought manufacturing companies with new possibilities to enhance their competitiveness and resilience. Shared manufacturing systems consist of agents such as manufacturing resources, and customer orders which pursue their individual objectives. Hence, despite its benefits, shared manufacturing systems come with computational challenges for effectively planning and scheduling this multi-agent ecosystem. Our study addresses this issue by introducing novel mixed integer programming (MIP) and constraint programming (CP) models as exact methods for representing and solving the scheduling of shared manufacturing resources. Additionally, a greedy constructive heuristic is developed. The effectiveness of the exact and heuristic methods is demonstrated through benchmarking with randomly generated instances.

an integrative optimization model to address assortment planning problem in a make-to-stock environment, leveraging customer substitution behaviors to mitigate supply and demand uncertainties. Our framework addresses the challenge of aligning product offerings with supply chain capabilities and customer preferences to maximize expected profit, while considering procurement and production capacity constraints. We formulate the problem as a multi-stage stochastic program with uncertain and time-varying demand, represented by multi-period look-ahead forecasts, as commonly observed in practice. Results are presented using data from an e-commerce furniture manufacturer and retailer.

3 - Data-Driven Dynamic Assortment Optimization with Product Returns

Recep Bekci

We consider assortment optimization in retail and online marketplaces. Our research integrates the dynamics of product returns into the process of assortment planning, proposing a data-driven approach that refines existing optimization practices, aiming to improved revenue management and reduced waste.

4 - Large-scale dynamic assortment planning problem: a heuristic approach

Mozart Menezes, Lijue Lu, Hamed Jalali

Single-period dynamic assortment planning refers to the retailer's problem of deciding the set of products to offer and their initial inventory levels with stochastic demand and dynamic substitution. The goal of the retailer is to maximize its expected revenue subject to a capacity constraint on the total number of items offered. This problem is notoriously difficult to solve. We propose an efficient heuristic for this problem considering an online retailer that has hundreds of possible SKUs to choose from and has the possibility to stock thousand units in total. We impose no assumptions on preference lists and substitution patterns. Compared to the most recent heuristic, our algorithm is competitive in the average revenue obtained but it is significantly faster especially for large instances. We show that our approach performs well in a variety of settings.

1 - Pricing and Inventory Decisions for an Assortment under a Generalized Nested Logit Choice

Bacel Maddah, Hussein Tarhini

We consider joint inventory and pricing decisions of substitutable products in an assortment that are differentiated by some primary and secondary attributes captured by a nested logit consumer choice. The choice model we consider is characterized by nests having different price elasticity parameters and dissimilarity indices, which generalizes recent work. On the supply side, we consider a newsvendor-type setting under Normal demand which is generated from an approximation to a Poisson arrival process. Motivated by results in the literature on the "riskless" case, which ignores inventory costs, we assume that the prices of all products in the assortment can be written as a function of a single decision variable. We verify that this simplifying assumption yield near-optimal results based on a detailed numerical study. We then analyze the properties of the expected profit at optimal inventory levels as a function of the pricing decision variable.

2 - Assortment Planning Optimization under Uncertainty with Customer-driven Product Substitution

Jisoo Park, Walid Klibi, Benoit Montreuil

The evolving retail landscape, marked by increasing production costs and resource constraints, highlights the need for assortment planning decisions made with supply chain considerations. Retail product manufacturers typically have their assortment decisions led by the marketing department, yet these are intricately linked to operational decisions across procurement, production, and inventory planning. We propose

Network Design and Line Planning for Public Transportation 1

Stream: Public Transport Optimization

Invited session

Chair: *Rowan Hoogervorst*

1 - Row and column generation for line planning under congestion

Rolf Van Lieshout, Yahan Lu, Layla Martin, Lixing Yang

This paper considers the problem of determining lines and frequencies in a public transport system. In comparison to existing approaches, we explicitly consider congestion and assume that passengers may choose different routes to reduce discomfort due to crowding. Our solution approach targets at finding a system-optimal solution by generating passenger routes in a dynamic fashion, whilst also adding cutting planes to deal with the non-linearity introduced by the congestion terms. Since passengers may deviate from system-optimal routes, line plans are evaluated by computing a user-equilibrium routing based on Wardrop's principle. Case studies demonstrate that incorporating congestion leads to fundamentally different line plans, that achieve a lower perceived travel time both for the system-optimal routing and for the user-equilibrium.

2 - An exact solution method for solving the line planning and frequency setting problem

Siv Marie Cartland Hansen, Evelien van der Hurk, Rowan Hoogervorst
